Abstract: It is shown that the representation theory of some finitely presented groups thanks to their $SL_2(\mathbb{C})$ character variety is related to algebraic surfaces. We make use of the Enriques–Kodaira classification of algebraic surfaces and related topological tools to make such surfaces explicit. We study the connection of $SL_2(\mathbb{C})$ character varieties to topological quantum computing (TQC) as an alternative to the concept of anyons. The Hopf link H, whose character variety is a Del Pezzo surface f_H (the trace of the commutator), is the kernel of our view of TQC. Qutrit and two-qubit magic state computing, derived from the trefoil knot in our previous work, may be seen as TQC from the Hopf link. The character variety of some two-generator Bianchi groups, as well as that of the fundamental group for the singular fibers $\tilde{E}_6$ and $\tilde{D}_4$ contain f_H. A surface birationally equivalent to a K_3 surface is another compound of their character varieties.

Keywords: $SL_2(\mathbb{C})$ character varieties; algebraic surfaces; magic state quantum computing; topological quantum computing; aperiodicity

1. Introduction

Let M be a three- or a four-manifold. An important invariant of M is the fundamental group $\pi_1(M)$. It classifies the equivalence classes under the homotopy of the loops contained in M. If M is the complement of a link or a knot embedded in the three-dimensional space, $\pi_1(M)$ is called a knot group. The Wirtinger representation explicitly describes the knot group with generators and relations based on a diagram of the knot.

In [1], the authors introduced a technique for describing all representations of a finitely presented group Γ in the group $SL_2(\mathbb{C})$. Representations of Γ in $SL_2(\mathbb{C})$ are homomorphisms $\rho : \Gamma \to SL_2(\mathbb{C})$. The character of a representation ρ is a map $\kappa_\rho : \Gamma \to \mathbb{C}$ defined by $\kappa_\rho(\gamma) = \text{tr}(\rho(\gamma))$, $\gamma \in \Gamma$. The set of characters of representations Γ in $SL_2(\mathbb{C})$ is $R(\Gamma) = \text{Hom}(\Gamma, SL_2(\mathbb{C}))$, which is a complex affine algebraic set. The set of characters is defined to be $X(\Gamma) = \{\kappa_\rho | \rho \in R(\Gamma)\}$.

Given a manifold M with fundamental group $\Gamma = \pi_1(M)$, one refers to the affine algebraic set $\tilde{X}(\pi_1(M))$ as the character variety of M. The character varieties of some three-manifolds of the Bianchi type were investigated in [2] and more generally in [3]. In the latter reference, a Sage software was developed to make the character variety explicit [4].

In the present paper, one finds that such character varieties decompose into algebraic surfaces that can be recognized through the Enriques–Kodaira classification [5]. Such surfaces are candidates for a new type of topological quantum computing different from anyons [6–8]. Related ideas are in [9,10]. A previous work of our group [11,12] proposed to relate the fundamental group of some three-manifolds to quantum computing, but did not employ the representation theory.

In Section 2, we introduce our mathematical concepts about algebraic surfaces, $SL_2(\mathbb{C})$ character varieties, and magic state quantum computing. The Hopf link H and the three-dimensional surface $f_H(x, y, z) = xyz - x^2 - y^2 - z^2 + 4$ lie at the "basement". In Section 3, we investigate the "floors" starting with the Whitehead link and its cousins in the Bianchi group family. Then, we find that the affine E_6 manifold—the two-covering of the affine E_8 manifold (also the zero-surgery on the trefoil knot)—and affine D_4 manifold—a three-covering—are other floors upon H and f_H. The $SL_2(\mathbb{C})$ character variety of $\tilde{E}_6$ is made of two K_3 surfaces in addition to f_H. In conclusion, we propose a few outlooks for future research.

2. Prolegomena

2.1. Algebraic Surfaces

Given an ordinary projective surface S in the projective space P^3 over a number field, if S is birationally equivalent to a rational surface, the software Magma [13] determines the map to such a rational surface and returns its type within five categories. The returned type of S can be the projective plane P^2, a quadric surface for a degree two surface in P^3, a rational ruled surface, a conic bundle, or a degree p Del Pezzo surface where $1 \leq p \leq 9$.

A further classification may be obtained for S in P^3 if S has at most point singularities. Magma computes the type of the non-singular projective surfaces in its birational equivalence class from the classification of Kodaira and Enriques [5]. The first returned value is the Kodaira dimension of S, which is $-\infty$, 0, 1, or 2. The second returned value further specifies the type within the Kodaira dimension $-\infty$ or 0 cases (and is irrelevant in the other two cases).

Birationally ruled surfaces have Kodaira dimension $-\infty$. The second returned value is the irregularity $q \geq 0$ of S. S is a rational surface that is birationally equivalent to a ruled surface over a smooth curve of genus q if and only if q is zero. Surfaces that are birationally equivalent to a torus, a bi-elliptic surface, a K_3 surface, or an Enriques surface have Kodaira dimension 0. While an elliptic surface can have Kodaira dimension $-\infty$, 0, or 1, all surfaces with Kodaira dimension 1 are elliptic surfaces (or quasi-elliptic in characteristics 2 or 3). Kodaira dimension two corresponds to algebraic surfaces of the general type.

2.2. The Hopf Link

Let us anticipate the details of our approach of connecting knot/link theory, algebraic surfaces, and topological quantum computing. One takes the linking of two unknotted curves as in Figure 1 (left), and the obtained link is called the Hopf link H = L2a1, whose knot group is defined as the fundamental group of the knot complement in the three-sphere S^3:

$$\pi_1(S^3 \setminus L2a1) = \langle a, b | [a, b] \rangle = \mathbb{Z}^2,$$ (1)

where $[a, b] = abAB$ (with $A = a^{-1}$, $B = b^{-1}$) is the group theoretical commutator.

There are interesting properties of the knot group π_1 of the Hopf link that we would like to mention.

First, the number of coverings of degree d of π_1 (which is also the number of conjugacy classes of index d) is precisely the sum of divisor function $\sigma(d)$ [14].

Second, there exists an invariance of π_1 under a repetitive action of the Golden mean substitution (the Fibonacci map) $\rho : a \to ab, b \to a$ or under the Silver mean substitution $\rho : a \to aba, b \to a$. The terms Golden and Silver refer to the Perron–Frobenius eigenvalue of the substitution matrix ([15], Examples 4.5 and 4.6). Such an observation links the Hopf link, the group π_1 of the two-torus, and aperiodic substitutions.

Using Sage software [4] developed by [3], the $SL_2(\mathbb{C})$ character variety is the polynomial:

$$f_H(x, y, z) = xyz - x^2 - y^2 - z^2 + 4.$$ (2)

As expected, the three-dimensional surface $\Sigma : f_H(x, y, z) = 0$ is the trace of the commutator and is known to correspond to the reducible representations ([16], Theorem 3.4.1). A picture is given in Figure 1 (right).

If we adopt the perspective of algebraic geometry by viewing Σ in the three-dimensional projective space as:

$$\Sigma_H(x, y, z, t) : xyz - t(x^2 + y^2 + z^2) + 4t^3 = 0, \qquad (3)$$

then Σ_H is a rational surface, more precisely a degree three Del Pezzo surface. It contains four simple singularities.

In [9], the author proposed the representation $\pi_1 \rightarrow SU(2) \otimes SU(2)$ as a model of two-qubit quantum computing in which each factor is associated with a single qubit located on each component of the Hopf link. Our project expands this idea by taking the representation $\pi_1 \rightarrow SL(2, \mathbb{C})$ and the attached character variety Σ_H as a model of topological quantum computing. Ideas in this direction are found in [17].
Figure 1. Left: the Hopf link. **Right**: a 3-dimensional picture of the $SL_2(\mathbb{C})$ character variety Σ_H for the Hopf link complement.

2.3. Magic State Quantum Computing

Since 2017, following the seminal paper [18], we have been developing a type of universal quantum computing based on magic states [19,20]. A magic state is a non-stabilizer pure state (a non-eigenstate of a Pauli group gate) that adds to stabilizer operations (Clifford group unitary operators, preparations, and measurements) in order to ensure the universality (the possibility of obtaining an arbitrary quantum gate). It has been recognized that some of the magic states are fiducial states for building a minimal informationally complete positive operator-valued measure (or MIC) of the corresponding Hilbert space dimension d, based on the action of the Pauli group $\mathcal{P}_d$ on the state.

The lower-dimensional case is the qutrit MIC arising from the fiducial state $f_{QT} = (0, 1, \pm 1)$. The next case is the two-qubit MIC arising from the fiducial state $f_{2QB} = (0, 1, -\omega_6, \omega_6 - 1)$ with $\omega_6 = \exp(\frac{2i\pi}{6})$. For such magic/fiducial states, the geometry of triple products of projectors $\Pi_i = |\psi_i\rangle\langle\psi_i|$ built with the d^2 outcomes ψ_i is the Hesse configuration (for qutrits: in dimension $d = 3$) and the $GQ(2, 2)$ configuration (for two qubits: in dimension $d = 2^2$) [19]. The latter configuration embeds the celebrated Mermin square configuration (a 3×3 grid of observables) needed to prove the Kochen–Specker theorem.

Our search for the magic states is performed with a two-generator infinite group G. A coset table over a subgroup H of index d is built by means of the Coxeter–Todd algorithm resulting in a permutation group. The latter may be seen as a $d \times d$ permutation matrix whose eigenstates are the candidates for a magic (and fiducial) state. We are dealing with low d values so that the choice is not large and many groups G do the job. Let us take G as the modular group $\Gamma = PSL(2, \mathbb{Z})$ as in [20]. Then, the appropriate subgroups are in the family of congruence subgroups $\Gamma_0(N)$ of level N defined as the subgroups of upper

triangular matrices with entries taken modulo N. The index of $\Gamma_0(N)$ is the Dedekind function $\psi(N)$. Thus, our relevant group for the qutrit magic state is the congruence subgroup $\Gamma_0(2)$, and for the two-qubit magic state, it is $\Gamma_0(3)$.

Next, the two groups of interest $\Gamma_0(2)$ and $\Gamma_0(3)$ may be seen as fundamental groups of non-hyperbolic three-manifolds [11]. It is known that Γ is isomorphic to the fundamental group $\pi_1(S^3 \setminus 3_1)$ of the trefoil knot complement. The subgroups of interest of $\pi_1(S^3 \setminus 3_1) \cong \Gamma$ are attached to links $L7n1$ and $L6a3$ ([12], Table 4). Their presentation is as follows:

$$\pi_1(S^3 \setminus L7n1) \cong \Gamma_0(2) = \langle a, b | [a, b^2] \rangle,$$
$$\pi_1(S^3 \setminus L6a3) \cong \Gamma_0(3) = \langle a, b | [a, b^3] \rangle.$$

Last but not least, in view of the presentation of the groups as commutators, the $SL_2(\mathbb{C})$ character variety of the two groups is that $f_H(x, y, z)$ of the Hopf link (apart for trivial factors y and $y^2 - 1$), as shown in Table 1. One concludes that universal quantum computing based on the magic states f_{QT} and f_{2QB} is essentially topological quantum computing over the Hopf link. The underlying algebraic geometry for these models is the surface drawn in Figure 1.

Table 1. Character varieties of fundamental groups whose reducible representations are that of the Hopf link. Column 1 identifies the group, as well as the corresponding link and 3- or 4-manifold. Column 2 is the name of the link or the relation it has to magic state quantum computing based on qutrits (QT) or two qubits (2QB). Column 3 is for the relation(s) of the two-generator fundamental groups. When the link is not the Hopf link, Column 4 is for the canonical component(s) of the representations and its (their) type as a surface in the 3-dimensional projective space.

Link L	Name	Rel(s) Link Group $\pi_1(L)$	Character Variety $f(x, y, z)$
L2a1	Hopf	$[a, b] = abAB$	$f_H = xyz - x^2 - y^2 - z^2 + 4$
-	-	-	deg 3 Del Pezzo
$\Gamma_0(2)$, L7n1	QT related	$[a, b^2]$	$y f_H$
$\Gamma_0(3)$, L6a3	2QB related	$[a, b^3]$	$(y^2 - 1) f_H$
$\Gamma_{-1}(12)$, L5a1	Whitehead	$ab^3 a^2 b AB^3 A^2 B$	$xy^2 z - y^3 - x^2 y - xz + 2y$
$ooct01_{00001}$	WL	-	conic bundle, K_3 type
$\Gamma_{-1}(12)$, L13n5885	sister WL	$a^2 b Ab^2 A^2 BaB^2$	$x^2 y^2 - xyz - x^2 + 1$
$ooct01_{00000}$	-	-	deg 4 Del Pezzo, K_3 type

$otet04_{00001}$	-	-	conic bundle, general type
$\Gamma_{-7}(6)$, L6a1	-	$abABa^2 BAb^3 ABabA^2 baB^3$	undetermined
$\tilde{E}_6$	IV^*	$a^3 b^3, ab^2 aBA^2 B$	$xy^3 - y^2 z - x^2 - 2xy + z + 2,$
-	-	-	$y^4 - x^2 z + xy - 4y^2 + z + 2$
-	-	-	K_3 type

3. Character Varieties for Fundamental Groups of Three-Manifolds and the Related Algebraic Surfaces

3.1. The $SL_2(\mathbb{C})$ Character Varieties of Knot Groups Whose Reducible Component Is that of the Hopf Link

We refer to some torsion-free subgroups of rank one of Bianchi groups. A Bianchi group $\Gamma_k = PSL(2, \mathcal{O}_k) < PSL(2, \mathbb{C})$ acts as a subset of orientation-preserving isometries of the three-dimensional hyperbolic space $\mathbb{H}_3$ with $\mathcal{O}_k$ the ring of integers of the imaginary quadratic field $\mathcal{I} = \mathbb{Q}(\sqrt{-k})$. A torsion-free subgroup $\Gamma_k(l)$ is the fundamental group π_1 of a three-manifold defined by a knot or a link such as the figure-of-eight knot (with $\Gamma_{-3}(12)$), the Whitehead link (with $\Gamma_{-1}(12)$), or the Borromean rings (with $\Gamma_{-1}(24)$). See [21,22] for more cases.

Looking at [22] (Table 1), We see that both the Whitehead link $L5a1$ and its sister $L13n5885$ (which have the same volume) are of the type $\Gamma_{-1}(12)$. They correspond to the three-manifolds ooct01$_{00001}$ and ooct01$_{00000}$, respectively. We are also interested in the links $L6a2 = 6^2_2$ (the Bergé link) and $L6a1 = 6^2_3$ [2], which are of the type $\Gamma_{-3}(24)$ and $\Gamma_{-7}(6)$, respectively. The latter link is related to the three-manifold otet04$_{00001}$.

The four links have fundamental groups of rank one as follows:

$$\pi_1(S^3 \setminus L5a1) = \langle a, b | ab^3 a^2 bAB^3 A^2 B \rangle,$$
$$\pi_1(S^3 \setminus L13n5885) = \langle a, b | a^2 bAb^2 A^2 BaB^2 \rangle,$$
$$\pi_1(S^3 \setminus L6a2) = \langle a, b | a^2 bAb^2 A^2 BaB^2 \rangle,$$
$$\pi_1(S^3 \setminus L6a1) = \langle a, b | ab^3 a^2 b^2 AB^3 A^2 B^2 \rangle.$$

Remarkably, as for the Hopf link, we find that the cardinality structure of conjugacy classes of subgroups (card seq) of the fundamental group $\pi_1(S^3 \setminus L)$ for the four links L is invariant under the repetitive action of the Golden mean and the Silver mean substitution. This points out an unexpected relationship of rank one Bianchi groups to aperiodicity.

The card seq of such four groups is

$$\eta_d(\pi_1(S^3 \setminus L5a1)) = [1, 3, 6, 17, 22, 79, 94, 412, 616, 1659, 2938, 10641, \cdots],$$
$$\eta_d(\pi_1(S^3 \setminus L13n5885)) = [1, 3, 5, 12, 19, 60, 44, 153, 221, 517, 632, 2223, \cdots],$$
$$\eta_d(\pi_1(S^3 \setminus L6a2)) = [1, 3, 4, 9, 24, 59, 71, 156, 262, 1208 \cdots],$$
$$\eta_d(\pi_1(S^3 \setminus L6a1)) = [1, 3, 7, 23, 28, 134, 184, 694, 1353, 3466 \cdots].$$

Unlike the case of $\pi_1(L)$ for the Hopf link $L =$L2a1, with links of the Bianchi family, the Golden and Silver mean maps do not preserve the original group. Only the card seq of $\pi_1(L)$ is invariant for the above four links.

We find that the three former links have a character variety with two components. The reducible component corresponds to the character variety of the Hopf link complement and, as described in the Introduction, is associated with a degree three Del Pezzo surface. The irreducible (or canonical component) is characterized below; see Table 1 for a summary.

Using Sage software [4] developed by [3], the $SL_2(\mathbb{C})$ character variety for the three links $L5a1$, $L13n5885$, and L6a2 factorizes as the product of two polynomials:

$$f_H(x, y, z) f(x, y, z),$$

where $f_H(x, y, z)$ is the character variety for the Hopf link complement as obtained in Section 2.2. The polynomial $f(x, y, z)$ consists of the irreducible $SL_2(\mathbb{C})$ representations of $\pi_1(L)$. For the Whitehead link, one obtains $f(x, y, z) = xy^2 z - y^3 - x^2 y - xz + 2y$. It is important to mention that the character variety for the group $\pi_1(L)$ depends on the selected Wirtinger representation. In [3] (Section 4.2), the relation for the fundamental group of the Whitehead link complement was taken to be $abaB[A, B]ABAb[a, b]$ instead of the one obtained from SnapPy [23] so that the canonical component of the character variety contains an extra third-order term.

Passing to the description of the surface $f(x, y, z)$ in the three-dimensional projective space as the homogeneous polynomial $\Sigma(x, y, z, t) = 0$, the main algebraic properties of Σ remain the same whatever the choice of the Wirtinger representation of $\pi_1(L)$. For the Whitehead link, we find that the surface Σ is birationally equivalent to a conic bundle with a Kodaira dimension zero. More precisely, Σ belongs to the family of K_3 surfaces.

Figure 2 provides the canonical component of the character variety for the links L13n5885 and L6a2, whose algebraic description is a degree four Del Pezzo surface of the K_3 family and a conic bundle of the general type, respectively. Unfortunately, we could not determine the character variety attached to the link L6a1.
Figure 2. The canonical component of character varieties for (**a**) the Whitehead link L5a1, (**b**) the Whitehead link sister L13n5885, and (**c**) the Bergé link L6a2.

3.2. The $SL_2(\mathbb{C})$ Character Variety of Singular Fiber $IV^* = \tilde{E}_6$

In [24], we found connections between Kodaira singular fibers and magic state quantum computing. The starting point of this viewpoint is the affine Coxeter–Dynkin diagram $\tilde{E}_8$, which corresponds to the fiber II^* in Kodaira's classification of minimal elliptic surfaces ([25], p. 320); see Figure 3. Alternatively, one can see $\tilde{E}_8$ as the 0-surgery on the trefoil knot 3_1. The fundamental group of affine E_8 manifold has the card seq:

$$\eta_d(\tilde{E}_8) = [1, 1, \mathbf{2}, \mathbf{2}, 1, \ \mathbf{5}, \mathbf{3}, 2, 4, 1, \ 1, 12, \mathbf{3}, 3, \mathbf{4}, \ \ldots] \tag{4}$$

where the bold characters mean that at least one of the subgroups of the corresponding index leads to a MIC. The Seifert fibered toroidal manifold is the boundary of the manifold associated with $\tilde{E}_8$ [26], denoted Σ' in [11] (Table 5).

(a)   (b)   (c)
Figure 3. A few singular fibers in Kodaira's classification of minimal elliptic surfaces. (**a**) Fiber I_0^* (alias $\tilde{D}_4$), (**b**) fiber IV^* (alias $\tilde{E}_6$), and (**c**) fiber II^* (alias $\tilde{E}_8$).

For this sequence, the coverings are fundamental groups of ([24], p. 20):

$$[\tilde{E}_8, \tilde{E}_6, \{\tilde{D}_4, \tilde{E}_8\}, \{\tilde{E}_6, \tilde{E}_8\}, \tilde{E}_8, \{BR_0, \tilde{D}_4, \tilde{E}_6\}, \{\tilde{E}_8\}, \{\tilde{E}_6\}, \{\tilde{D}_4, \tilde{E}_8\}, \tilde{E}_6, \cdots]$$

The subgroups/coverings are fundamental groups for $\tilde{E}_8$ $\tilde{E}_6$, $\tilde{D}_4$, or BR_0, where BR_0 is the manifold found from zero-surgery on all circles of Borromean rings.

One sees that the singular fiber $IV^* = \tilde{E}_6$ appears as the degree two covering of $II^* = \tilde{E}_8$. The fundamental group is

$$\pi_1(S^4 \setminus \tilde{E}_6) = \left\langle a, b | a^3 b^3, ab^2 aBA^2 B \right\rangle, \tag{5}$$

where S^4 is the four-sphere.

We already found an invariance of the card seq of $\pi_1(L)$ under the Golden mean substitution (the Fibonacci map) or under the Silver mean substitution when L is the Hopf link and when $\pi_1(L)$ is in the Bianchi family of two-generator groups. We now observe that this invariance is preserved when L is the trefoil knot 3_1, its surgery $\tilde{E}_8 = 3_1(0,1)$ and $\tilde{E}_6$. Aperiodicity is a feature of all the fundamental groups we have encountered so far.

Using Sage software [4], the $SL_2(\mathbb{C})$ character variety of group $\pi_1(S^4 \setminus \tilde{E}_6)$ factorizes as the polynomial product:

$$f_H(x, y, z)(x - y)(xy - z + 1)(x^2 + xy + y^2 - 3)f_1(x, y, z)f_2(x, y, z),$$

where $f_H(x, y, z)$ is the $SL_2(\mathbb{C})$ character variety for the fundamental group of the Hopf link complement, $f_1(x, y, z) = xy^3 - y^2 z - x^2 - 2xy + z + 2$ and $f_2(x, y, z) = y^4 - x^2 z + xy - 4y^2 + z + 2$. A plot of the latter surfaces is in Figure 4.

Passing to the description of the surfaces $f_1(x, y, z)$ and $f_2(x, y, z)$ in the three-dimensional projective space as $\Sigma_1(x, y, z, t)$ and $\Sigma_2(x, y, z, t)$, we find that Σ_1 is birationally equivalent to a conic bundle and Σ_2 to the projective plane P^2. Both surfaces show a Kodaira dimension 0 characteristic of K_3 surfaces.

The magic states from $\eta_d(\tilde{E}_8)$ at index 3 and 4 are f_{QT} and f_{2QB}, as in Section 2.3 for the manifolds L7n1 and L6a3, but their algebraic geometry is not the Hopf link. The associated $SL_2(\mathbb{C})$ character varieties are found to contain quadric surfaces $y - z^2 + 2$ (as for $\eta_d(\tilde{E}_8)$ itself) and $x^2 + xy + y^2 - 3$, respectively.

Thus, the existence of a magic state is not sufficient for the issue of topological quantum computing. The concept of the $SL_2(\mathbb{C})$ character variety of the fundamental group adds topological and algebraic features not present in the fundamental group of the manifold. In this respect, the affine E_6 manifold (the singular fiber IV^*) is a potential candidate.
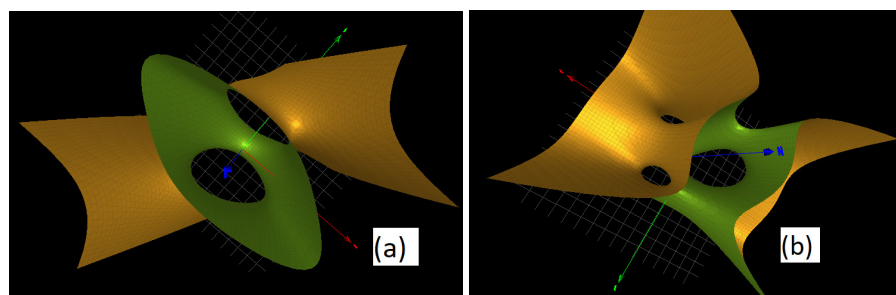

Figure 4. The surfaces $f_1(x, y, z)$ in (**a**) and $f_2(x, y, z)$ in (**b**) belonging to the character variety of singular fiber $IV^* = \tilde{E}_6$. Both surfaces are birationally equivalent to K_3 surfaces.

3.3. The $SL_2(\mathbb{C})$ Character Variety of Singular Fiber $I_0^* = \tilde{D}_4$

Singular fibers occur inside a (minimal) elliptic fibration. Let us pass to the generic elliptic fiber I_0, a torus, and to the singular fiber $I_0^* = \tilde{D}_4$ shown in Figure 3a. A neighborhood of the singular fiber inside a K_3 surface leads to a plumbing diagram that is precisely I_0^* ([25], Figure 3.15, p. 133).

As shown in the previous section, the link $\tilde{D}_4$ corresponds to the cyclic covering of degree three of $\pi_1(\tilde{E}_8)$. The fundamental group is

$$\pi_1(S^4 \setminus \tilde{D}_4) = \left\langle a, b, c \,|\, a^2 c^2, b^2 c^2, aBCaBc \right\rangle. \tag{6}$$

For this the three-generator group, the $SL_2(\mathbb{C})$ character variety is made of seven variable polynomials. Making use of the software available in [4], it has the form

$$
\begin{aligned}
f(k, x, y, z, u, v, w) = &(f_H(x, y, z) + wxk - 2k^2) \\
&(uk^2 + vx - 2u)(vk^2 + ux - 2v)(wk^2 + xk - 2W)(k^3 + wx - 2k) \\
&(u^2 - k^2)(uv - wk)(v^2 - k^2)(uw - vk)(vw - uk)(w^2 - k^2)(uy - 2w) \\
&(vy - 2k)(wy - 2u)(uz - 2k)(vz - 2w)(wz - 2v)(yk - 2v)(zk - 2u),
\end{aligned}
$$

where $f_H(x, y, z)$ is the Hopf link polynomial of Section 2.2.

Thus, a section at constant w and k of the character variety for the link $\tilde{D}_4$ is simply a deformation of the character variety for the Hopf link, apart from trivial linear or quadratic polynomials.

As for the other links L encountered so far, there exists an invariance of the card seq of $\pi_1(L)$ when $L = \tilde{D}_4$. Let us apply the map $a \to b$, $b \to abc$, $c \to a$ on the three generators of L; the substitution map $T = \begin{pmatrix} 0 & 1 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix}$ is primitive since $T^3 >> 0$, and the Perron–Frobenius eigenvalue is the real root of the polynomial $\lambda^3 - 2\lambda + 1 = 0$, that is $\lambda_{PF} \sim 1.83928$, the Tribonacci constant [27]; see also [15,28] (Section 4) for the mathematical details. This reveals the aperiodicity of the fundamental group.

4. Conclusions

We discovered connections between the $SL_2(\mathbb{C})$ character varieties for the fundamental groups of some links, the theory of algebraic surfaces, and topological quantum computing. Our study was based on the Hopf link and links showing the Hopf link character variety as a component. In particular, we were concerned with links in the Bianchi family (such as the Whitehead link) and links for singular fibers in an elliptic fibration. The former define three-dimensional manifolds, while the latter correspond to four-dimensional manifolds.

Our approach may connect to some theories of topological quantum field theory [29] and quantum gravity [30,31]. In particular, in loop quantum gravity [31], the quantum states of the gravitational field are described by a map between $SU(2)$ and $SL_2(C)$ representations, the topological quantum computing aspects of which can be exploited.

One starting point for future investigations may start from [32], where several mathematical connections of character varieties to other branches of mathematics were proposed. In particular, Cayley's nodal cubic surface described as Equation (1) is in the family of smooth symmetric Fricke cubic surfaces [33]. The latter are isomorphic to a two-parameter family of character varieties for the exceptional group $G_2(\mathbb{C})$. The group $G_2(\mathbb{C})$ arises as the group of automorphisms of the complex octonions; its (unique) semisimple conjugacy class is six-dimensional and relates to the E_8 root lattice thanks to the Fano plane representation of octonions. Three elements of $G_2(\mathbb{C})$, obtained from three lines passing through a single point in the Fano plane, generate a finite simple subgroup of $G_2(\mathbb{C})$ isomorphic to $G_2(2)' \cong U_3(3)$ of order 6048.

Next, the group $U_3(3)$ stabilizes the split Cayley hexagon $GH(2,2)$—a $[63_3]$ configuration —and its dual ([34], Table 8). The 63 points of the hexagon may be encoded with three-qubit Pauli observables [35]; the hexagon embeds $12,096 = 2 \times 6048$ Mermin pentagrams (proofs of the Kochen–Specker theorem), which correspond to the number of automorphisms of $G_2(2)$ [36], and finally, the dual of the hexagon is obtained from the triple products of projectors defining the Hoggar SIC-POVM (symmetric informationally complete positive operator-valued measure) ([19,37], Section 2.6 and Figure 3).
