The use of antimicrobial peptides (AMPs) covalently grafted on surfaces has been recognized in recent years as a promising strategy to fight against biofilms formation. However, after grafting, the understanding of AMPs-bacteria interactions is still debated in the literature. In this study, **Ruminococcin C (RumC)** and **Nisin (Nis)** were covalently immobilized on silicon and gold surfaces to study and compare their bactericidal activity against two bacterial species : *Staphylococcus aureus* (Gram+ bacterium) and *Escherichia coli* (Gram- bacterium).

NISIN

Nisin 3D structure
34 AA

Lantibiotic, cyclic AMP.

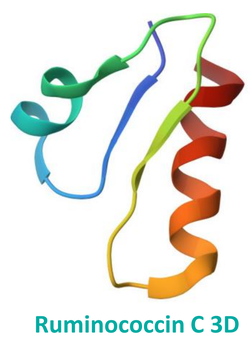
Produced by ***Lactococcus lactis***

5 thioether rings : Ala 3 - Ala 6, **Ala** 11 - Abu 7, **Ala** 19 - Abu 13, **Ala** 26 -Abu 23, **Ala** 28 - Abu 24

Mechanism of action : binds lipid II, blocks cell wall synthesis, and forms pores that cause leakage and rapid cell death → **rapid effect**.

Antimicrobial spectrum : broadly active against **Gram-positive bacteria,** limited or no activity against **Gram-negatives**.

RUMINOCOCCIN C



Ruminococcin C 3D structure
44 AA

Sactipeptide, double-hairpin structure.

Produced by ***Ruminococcus gnavus* E1,** from human gut symbiot.

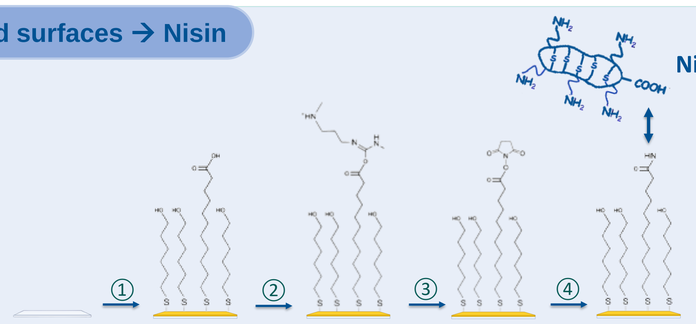
4 sulfur-to-α-carbon thioether bridges : **Cys** 3 - Asn 16, **Cys** 5 – Ala 12, **Cys** 22 - Lys 42, **Cys** 26 - Arg 34

Mechanism of action : binds lipid II and inhibits cell wall synthesis and essential biosynthetic pathways (DNA, RNA, ATP) but does **not** form pores → **slow effect**.

Antimicrobial spectrum : effective against several **Gram-positive** pathogens, small activity against some **Gram-negative species.**

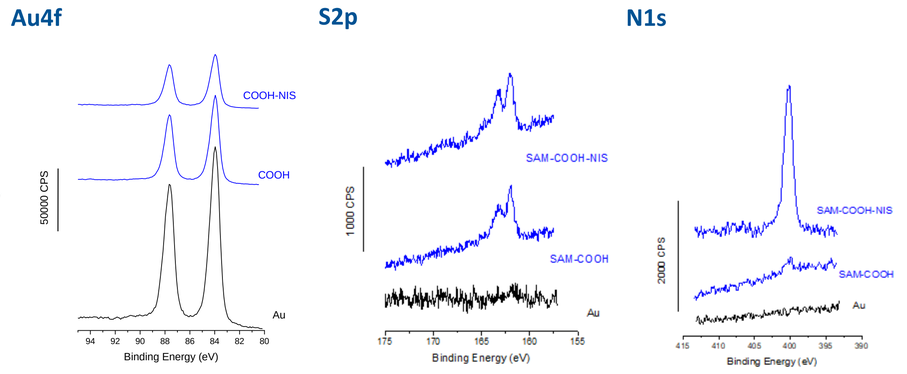
GRAFTING STRATEGY

Gold surfaces → Nisin

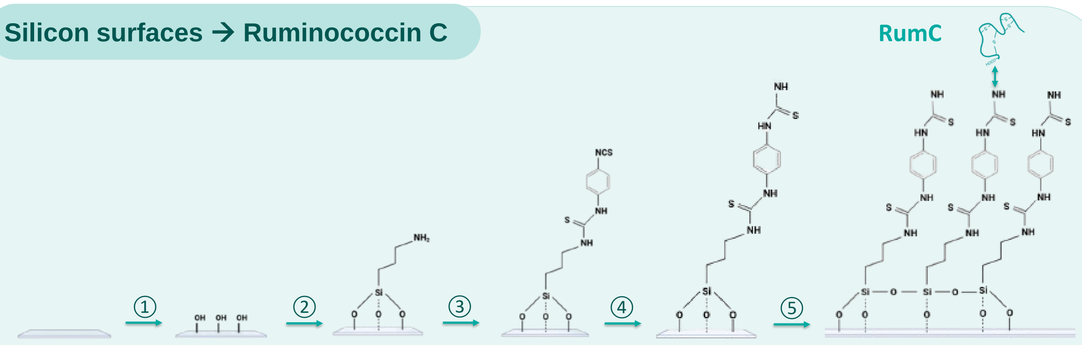


Cathodic deposition of gold layer on glass ① before creation of a thiols Self-Assembled Monolayer (SAM) ②, then activated thanks to carboxylic function ③ before Nisin molecule grafting ④.

XPS

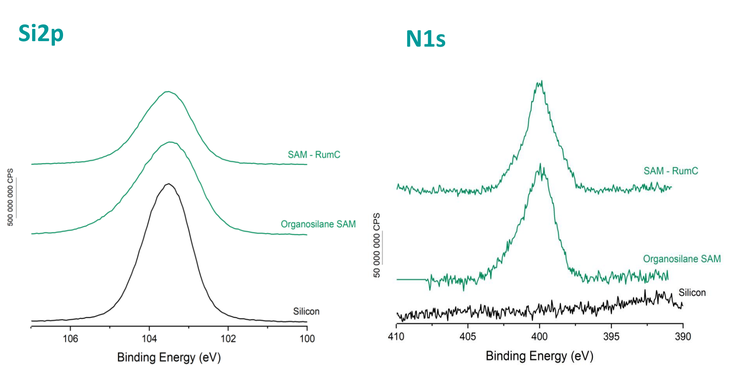


Silicon surfaces → Ruminococcin C



Plasma activation of silicon surface ① before creation of an organosilane Self-Assembled Monolayer (SAM) ②.
Grafting of a thiocyanate spacer ③ before Ruminococcin molecule grafting ④.

XPS



Quantification
(equivalent thicknesses)

$n\text{-}S_{COOH}$ = 5,6 /nm²

$n\text{-}Nis_{S/COOH}$ = 0,55 /nm²

$n\text{-}APTES_{Si}$ = 33 /nm²

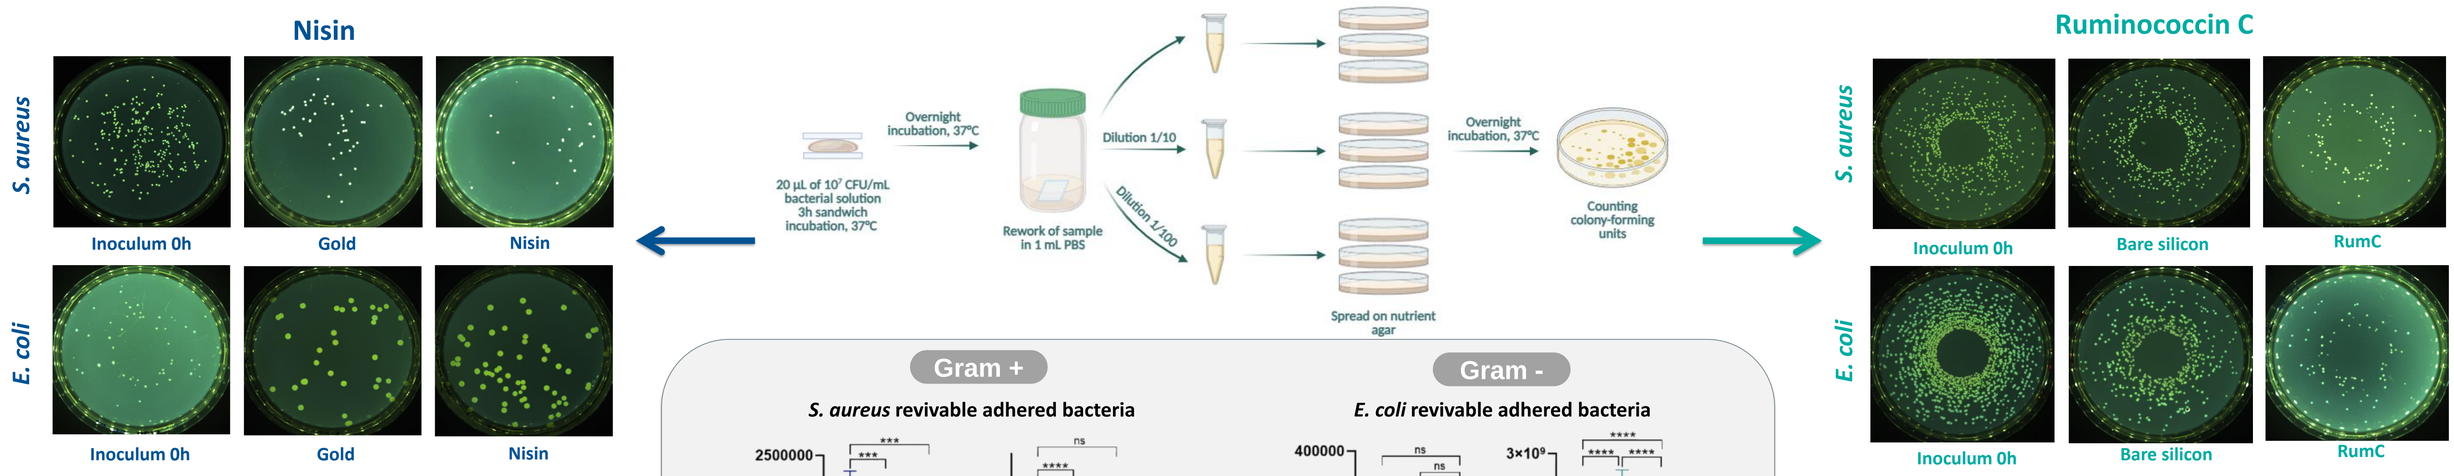
$n\text{-}RumC_{APTES}$ = 1,9 /nm²

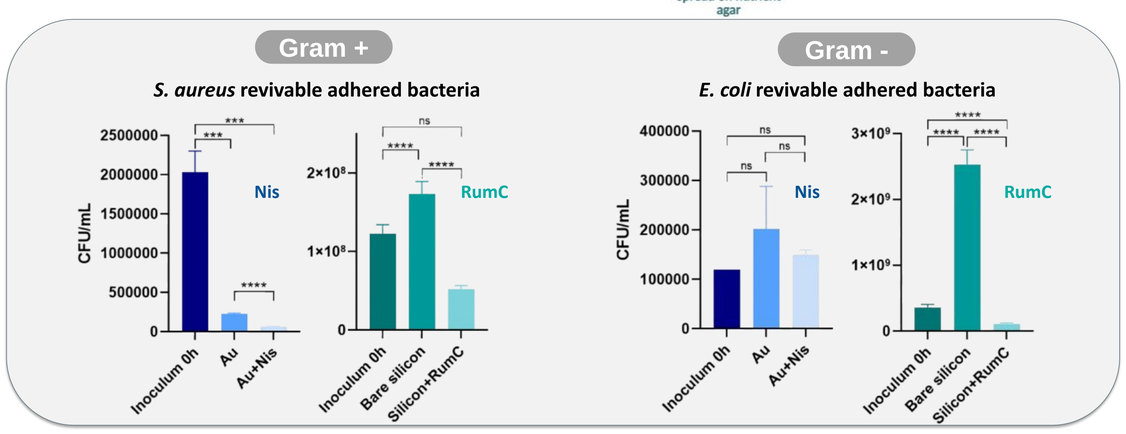
Large rate of **APTES** molecules on silicones :

- high roughness of the silicone surface (breast prothesis)
- **APTES** forms a **dense layer** on the surface, unlike **thiols**, which are **ordered**

4 x more RumC on surfaces

MICROBIOLOGICAL ANTIBACTERIAL TESTS





Nisin	% Killing/inoculum	% Killing/ref. surface (i.e. gold surface)
Staphylococcus aureus	96,8	72,2
Escherichia coli	< 0	23,2

RumC	% Killing/inoculum	% Killing/ref. surface (*i.e.* bare silicon)
Staphylococcus aureus	73,6	76,9
Escherichia coli	83,2	89,78

CONCLUSION & PROSPECTS

Both AMPs **effective against *S. aureus* bacteria** on surfaces, as expected. Concerning **Gram-negative bacterium**, **Nisin** has **no real activity against *E. coli***, as expected, but **RumC** is **effective against *E. coli***. RumC seems to be a better antibacterial peptide to use to prevent biofilm formation.

Next, antimicrobial activity would be done on **titanium surfaces** (to mimic implants surfaces) and a serie of experiments would be performed with **mammalian cells** to evaluate the **cytotoxicity** of the AMPs, on silicon and titanium surfaces. Moreover, bacterial concentration used in this study is 10^7 CFU/mL, far away from reality. Indeed, it could be interesting to determine the **bactericidal effect at lower concentration**, miming a more realistic concentration in case of infection (about 10^3 CFU/mL).
Finally, as the mechanisms of action of the two AMPs are different, it would be interesting to evaluate the antibacterial activity over time (from hours to several days).

This work was partly supported by the French RENATECH network and its FEMTO-ST technological facility.
