Abstract. This paper addresses the following general problem of tree regular model-checking: decide whether $R(L) \setminus L_p = \emptyset$ where $R$ is the reflexive and transitive closure of a successor relation induced by a term rewriting system $R$, and $L$ and $L_p$ are both regular tree languages. We develop an automatic approximation-based technique to handle this – undecidable in general – problem in most practical cases, extending a recent work by Feuillade, Genet and Viet Triem Tong. We also make this approach fully automatic for practical validation of security protocols.

Key-words: Verification, model-checking, regular languages, security protocols.
Computing Reviews Categories: D.2.4 and F.4.2.

1. Introduction

Automatic verification of software systems is one of the most challenging research problems in computer aided verification. In this context, regular model-checking has been proposed as a general framework for analysing and verifying infinite state systems. In this framework, systems are modelled using regular representations: the systems configurations are modelled by finite words or trees (of unbounded size) and the dynamic behaviour of systems is modelled either by a transducer or a (term) rewriting system. Afterwards, a system reachability-based analysis is reduced to the regular languages closure computation under (term) rewriting systems: given a regular language $L$, a relation $R$ induced by a (term) rewriting system and a regular set $L_p$ of bad configurations, the problem is to decide whether $R(L) \cap L_p = \emptyset$ where $R$ is the reflexive and transitive closure of $R$. Since $R(L)$ is in general neither regular nor decidable, several approaches handle restricted cases of this problem.

In this paper we address this problem for tree regular languages by automatically computing over- and under-approximations of $R^*(L)$. Computing an over-approximation $K_{\text{over}}$ of $R^*(L)$ may be useful for the problem if $K_{\text{over}} \cap L_p = \emptyset$, proving that $R^*(L) \cap L_p = \emptyset$. Dually, under-approximation may be suitable to prove that $R^*(L) \cap L_p \neq \emptyset$. This approach is relevant if the computed approximation are not too coarse. Another important point is that in general, there are some
restrictions on the rewriting systems in order to ensure the soundness of the above approach. This paper 1) generalises this approach for any kind of term rewriting systems, and 2) describes its successful application for the security protocol analysis.

1.1 Contributions

This paper extends an expert-human guided approximation technique introduced in [Feuillade et al. 2004] for left-linear term-rewriting systems. The contributions of this paper are:

1. We show how to extend the over-approximation approach of [Feuillade et al. 2004] to all term rewriting systems,

2. We show how the under-approximation approach of [Feuillade et al. 2004] may be extended to a suitable sub-class of non-left-linear term-rewriting systems,

3. We explain how 1. can be efficiently implemented, particularly for quadratic rewriting rules that are very useful in practice.

4. We explain how to make the approach fully automatic and how to successfully exploit this approach in the context of security protocols verification.

Notice that 1. and 2. were respectively presented in [Boichut et al. 2006] and in [Boichut et al. 2007] without proofs nor explicit examples.

1.2 Related Works

Model checking is a central verification technique based on state exploration. Since for infinite state systems an exhaustive exploration is impossible, several symbolic techniques (consisting in representing infinite sets of states by a symbolic finite representation) have been developed.

1.2.1 Regular Model Checking

Regular Model Checking (RMC for short) is a symbolic approach using finite automata [Abdulla et al. 1998] [Boigelot and Wolper 1998] [Boigelot and Godefroid 1996] [Pnueli and Shahar 2000] [Jonsson and Nilsson 2000] [Dams et al. 2002] (and sometimes regular expressions [Bouajjani et al. 2001]) in order to encode infinite sets of states. Most of these works deal with word automata (see [Finkel and Leroux 2002] for automata with Presburger constraints, [Bardin et al. 2004] for automata with counters, [Finkel et al. 1997] for pushdown automata, etc). These techniques have been successfully used for verifying mutual exclusion protocols [Touili 2001], for lossy communicating system modelling and verification [Abdulla et al. 1999] [Cece and Finkel 2005] or for static analysis of programs [Bouajjani et al. 2003] [Gall and Jeannet 2007].

Tree data structures are more complex objects, and adapting or developing new techniques remains a deep challenge. In [Bouajjani and Touili 2002][Bouajjani et
al. 2005] [Bouajjani et al. 2006][Abdulla et al. 2006], authors show how to extend some word techniques to tree data structures.

1.2.2 Term Rewriting Systems and Reachability Analysis on Regular Languages

Given a term rewriting system \( \mathcal{R} \) and two ground terms \( s \) and \( t \), deciding whether \( s \rightarrow^*_{\mathcal{R}} t \) is a central question in automatic proof theory. This problem is shown decidable for term rewriting systems which are terminating but it is undecidable in the general case. Several syntactic classes of term rewriting systems have been pointed out to have a decidable accessibility problem, for instance by providing an algorithm to compute \( \mathcal{R}^*(L) \) when \( L \) is a regular tree language [Dauchet and Tison 1990] [Coquidé et al. 1991] [Gilleron and Tison 1995] [Jacquemard 1996] [Réty and Vuotto 2002] [Salomaa 1988].

In [Feuillade et al. 2004], authors focus on a general completion based human-guided technique. This technique has been successfully used (not automatically) to prove the security of cryptographic protocols [Genet and Klay 2000] and recently Java Bytecode programs [Boichut et al. 2007]. This framework was extended in [Ohsaki and Takai 2004] to languages accepted by AC-tree automata.

1.2.3 Verification of Security Protocols

The challenge we want to take on is to automate [Feuillade et al. 2004] for the security protocol verification in a very general context. Cryptographic protocols are widely used to secure information exchange over open modern networks. It is now widely accepted that formal analysis can provide the level of assurance required by protocols both the developers and the users. But, whatever the used formal model, analysing cryptographic protocols is a complex task because the set of configurations to consider is very large, and can even be infinite. Indeed, any number of sessions (sequential or parallel executions) of protocols, sessions interleaving, any size of messages, algebraic properties of encryption or data structures give rise to infinite-state systems. In the context of protocols verification, the security problem we are dealing with consists in deciding whether a protocol preserves secrecy against an intruder, or not.

Complexity Issues. For this problem, current model-checking based verification methods can be applied whenever the number of participants and the number of sessions between the agents are bounded. In this case, the protocol security problem is co-NP-complete [Rusinowitch and Turuani 2001]. The work in [Truderung 2005] presents new decidability results for a bounded number of sessions, restricted to the case where the initial knowledge of the intruder is a regular language and under the assumption that the keys used in protocols are atomic. When the number of sessions is unbounded, the security problem of cryptographic protocols becomes undecidable, even when the length of the messages is bounded [Durgin et al. 1999]. Decidability can be recovered by adding some restrictions to protocols as, for instance, in [Comon-Lundh and Cortier 2005]. Another way to circumvent
the problem is to employ abstraction-based approximation methods [Monniaux 1999][Genet and Klay 2000].

Close Works on Automated Protocol Analysis. An independent work close to our approach is presented in [Zunino and Degano 2006] where authors use a process algebra based model and constraints-guided over-approximations. This approach has been successfully applied to the complex Kerberos protocol. However, [Zunino and Degano 2006] does not presently handle under-approximations.

There already exists a number of tools in the literature that provide automated semi-decision procedures for security protocols with an unbounded number of sessions: Blanchet’s ProVerif, Ernie Cohen’s TAPS, Isabelle proof assistant for the Protocol Composition Logic (PCL) from Stanford.

The CL-AtSe tool (Constraint Logic based Attack Searcher) [Chevalier et al. 2005] now supports complete analysis of cryptographic protocols modulo the xor, including all the intruder deduction rules for that operator, and modulo the exp except for the rule $g_1 = g_2$ (i.e. exponentials are tagged). CL-AtSe analyses are performed for a bounded number of sessions.

The On-the-fly Model-Checker (OFMC) [Basin et al. 2003] tool-set, is based on two symbolic techniques and now supports the specification of cryptographic operators algebraic properties, and typed or untyped protocol models, in the context of a bounded number of sessions. For verifying security protocols without bounding the number of sessions, Mödersheim [2007] develops an abstract interpretation based approach.

The Proverif tool [Blanchet 2001] allows an unbounded number of sessions but – like in our models – abstractions are performed on fresh data and thus false attacks can be detected. Moreover, in [Blanchet et al. 2007], the authors note that their technique does have limitations, and in particular, it does not apply to some equational theories.

The recent Scyther tool [Cremers 2006] can verify protocols with an unbounded number of sessions and nonces. It can handle verification of complex authentication properties, handle non-atomic keys, and generate correct attacks. A perfor-
mance comparison between Scyther and a number of other tools has been detailed in [Cremers and Lafourcade 2007]. Notice that [Cremers and Lafourcade 2007] reports on a set of protocols that excludes protocols using algebraic properties.

One of the new features of the Maude-NPA tool is that it allows to equational-ally reason about security when facing attempted attacks on low-level algebraic properties of the functions used in a protocol such as, for example, associativity-commutativity, Boolean theory, and some forms of modular exponentiation [Escober et al. 2007]. The Maude-NPA tool follows an approach similar to that of OFMC since the authors consider depth parameters for unification problems in some equational theories. However, the Maude-NPA tool needs the help of expert users.

In the survey [Cortier et al. 2006], the authors emphasise the fact that the results often remain theoretical, and very few implementations automatically verify protocols with algebraic properties.

1.3 Layout of the paper

Section 2 introduces notations and the basic completion approach. Next, Section 3 presents the main theoretical contributions of the paper. We introduce the notion of $(l \rightarrow r)$-substitutions in Section 3.1. We show how it can be used to develop an over-approximation based technique for tree regular model-checking in Section 3.2. The case of under-approximations is handled in Section 3.4, while Section 3.3 is dedicated to an example. Section 4 exposes how the techniques are successfully exploited for analysing security protocol.

2. Formal Background

As for prerequisites, the reader is expected to be familiar with basic notions on term rewriting systems and tree automata. We just recall the terminology which is consistent with [Comon et al. 2002], thus making our exposition as self-contained as possible.

2.1 Notations

Given the set $\mathbb{N}$ of natural integers, $\mathbb{N}^*$ denotes the finite strings over $\mathbb{N}$. Let $\mathcal{F}$ be a finite set of symbols, associated with an arity function $\text{ar} : \mathcal{F} \rightarrow \mathbb{N}$. The set of symbols of $\mathcal{F}$ of arity $i$ is denoted $\mathcal{F}_i$. Let $\mathcal{X}$ be a countable set of variables. We assume that $\mathcal{X} \cap \mathcal{F} = \emptyset$. $\mathcal{T}(\mathcal{F}, \mathcal{X})$ denotes the set of terms, and $\mathcal{T}(\mathcal{F})$ denotes the set of ground terms (terms without variables).

A finite ordered tree $t$ over a set of labels $(\mathcal{F}, \mathcal{X})$ is a function from a prefix-closed set $\mathcal{Pos}(t) \subseteq \mathbb{N}^*$ to $\mathcal{F} \cup \mathcal{X}$. A term $t$ over $\mathcal{F} \cup \mathcal{X}$ is a labelled tree whose domain $\mathcal{Pos}(t)$ satisfies the following properties: 1) $\mathcal{Pos}(t)$ is non-empty and prefix closed, 2) for each $p \in \mathcal{Pos}(t)$, if $t(p) \in \mathcal{F}_n$ (with $n \neq 0$), then $\{i \mid p.i \in \mathcal{Pos}(t)\} = \{1, \ldots, n\}$, and 3) for each $p \in \mathcal{Pos}(t)$, if $t(p) \in \mathcal{X}$ or $t(p) \in \mathcal{F}_0$, then $\{i \mid p.i \in \mathcal{Pos}(t)\} = \emptyset$. The empty sequence $\epsilon$ denotes the top-most position.
Each element of $\mathcal{P}os(t)$ is called a position of $t$. For each subset $\mathcal{K}$ of $\mathcal{T} \cup \mathcal{X}$ and each term $t$ $\mathcal{P}os_{\mathcal{K}}(t)$ is the subset of positions $p$’s of $t$ such that $t(p) \in \mathcal{K}$. Each position $p$ of $t$ such that $t(p) \in \mathcal{T}$, is called a functional position.

A subterm $t_{ip}$ of $t \in \mathcal{T}(\mathcal{F}, \mathcal{X})$ at position $p$ is defined by the following: $\mathcal{P}os(t_{ip}) = \{ i | p.i \in \mathcal{P}os(t) \}$, and for all $j \in \mathcal{P}os(t_{ip})$, $t_{ip}(j) = t(p.j)$. The term $t[s]_{ip}$ is obtained from $t$ by replacing the subterm $t_{ip}$ by $s$. $\mathcal{V}ar(t)$ is the set of variables occurring within $t$ and is formally defined as follows: $\mathcal{V}ar(t) = \{ t(p) | p \in \mathcal{P}os(t) \wedge t(p) \in \mathcal{X} \}$.

For all sets $A$ and $B$, we denote by $\Sigma(A, B)$ the set of functions from $A$ to $B$. If $\sigma \in \Sigma(\mathcal{X}, B)$, then for each term $t \in \mathcal{T}(\mathcal{F}, \mathcal{X})$, the term $t \sigma$ is obtained from $t$ by replacing for each $x \in \mathcal{X}$, the variable $x$ by $\sigma(x)$.

A term rewriting system (TRS for short) $\mathcal{R}$ over $\mathcal{T}(\mathcal{F}, \mathcal{X})$ is a finite set of pairs $(l, r)$ from $\mathcal{T}(\mathcal{F}, \mathcal{X}) \times \mathcal{T}(\mathcal{F}, \mathcal{X})$, written $l \rightarrow r$, such that the set of variables occurring in $r$ is included in the set of variables of $l$. A TRS is left-linear if for each rule $l \rightarrow r$, every variable occurring in $l$ occurs once at most. For each ground term $t$, we denote by $\mathcal{R}(t)$ the set of ground terms $t'$ such that there exist a rule $l \rightarrow r$ of $\mathcal{R}$, a function $\mu \in \Sigma(\mathcal{X}, \mathcal{T}(\mathcal{F}))$ and a position $p$ of $t$ satisfying $t_{ip} = \mu l$ and $t' = t[\mu]_{ip}$. The relation $\{(t, t') | t' \in \mathcal{R}(t)\}$ is classically denoted $\rightarrow_{\mathcal{R}}$. If $t \rightarrow_{\mathcal{R}} t'$ for $t, t' \in \mathcal{T}(\mathcal{F})$, then $t$ is a rewriting predecessor of $t'$ and $t'$ is rewriting successor of $t$. For a set of ground terms $B$, $\mathcal{R}^+(B)$ is the set of ground terms related to an element of $B$ modulo the reflexive-transitive closure of $\rightarrow_{\mathcal{R}}$.

A tree automaton $\mathcal{A}$ is a tuple $(Q, \Delta, F)$, where $Q$ is the set of states, $\Delta$ the transition set, and $F$ the set of final states. Transitions are rewriting rules of the form $f(q_1, \ldots, q_k) \rightarrow q_{k+1}$, where $f \in \mathcal{T}_k$ and the $q_i$’s are in $Q$. Such transitions are so called normalised transitions. A term $t \in \mathcal{T}(\mathcal{F})$ is accepted or recognised by $\mathcal{A}$ if there exists $q \in F$ such that $t \rightarrow^* \mathcal{A} q$ (we also write $t \rightarrow^* \mathcal{A} q$). The set of terms accepted by $\mathcal{A}$ is denoted $\mathcal{L}(\mathcal{A})$. For each state $q \in Q$, we write $\mathcal{L}(\mathcal{A}, q)$ for the tree language $\mathcal{L}((Q, \Delta, \{ q \}))$. A tree automaton is finite if its set of transitions is finite.

### 2.2 Completion

Given a tree automaton $\mathcal{A}$ and a TRS $\mathcal{R}$, for several classes of automata and TRSs, the tree automata completion algorithm computes a tree automaton $\mathcal{A}_k$ such that $\mathcal{L}(\mathcal{A}_k) = \mathcal{R}^+(\mathcal{L}(\mathcal{A}))$ when it is possible and such that $\mathcal{L}(\mathcal{A}_k) \supseteq \mathcal{R}^+(\mathcal{L}(\mathcal{A}))$ otherwise [Genet and Klay 2000][Feuillard et al. 2003]. The tree automata completion works as follows. From $\mathcal{A} = \mathcal{A}_0$ the completion builds a sequence $\mathcal{A}_0, \mathcal{A}_1, \ldots, \mathcal{A}_k$ of automata such that if $s \in \mathcal{L}(\mathcal{A}_i)$ and $s \rightarrow_{\mathcal{R}} t$ then $t \in \mathcal{L}(\mathcal{A}_{i+1})$. If the automaton $\mathcal{A}_k$ is a fixpoint, i.e. if $\mathcal{R}(\mathcal{L}(\mathcal{A}_k)) = \mathcal{L}(\mathcal{A}_k)$, then we have $\mathcal{L}(\mathcal{A}_k) = \mathcal{R}^+(\mathcal{L}(\mathcal{A}_0))$ (or $\mathcal{L}(\mathcal{A}_k) \supseteq \mathcal{R}^+(\mathcal{L}(\mathcal{A}))$ if $\mathcal{R}$ is not in one class of [Feuillard et al. 2003]). To build $\mathcal{A}_{i+1}$ from $\mathcal{A}_i$, a completion step is performed which consists in finding critical pairs between $\rightarrow_{\mathcal{R}}$ and $\rightarrow_{\mathcal{A}_i}$. For a substitution $\sigma : \mathcal{X} \mapsto Q$ and a rule $l \rightarrow r \in \mathcal{R}$, a critical pair is an instance $lr$ of $l$ such that there exists $q \in Q$ satisfying $l \sigma \rightarrow_{\mathcal{A}_i} q$ and $r \sigma \not\rightarrow_{\mathcal{A}_i} q$. For every critical pair $l \sigma \rightarrow_{\mathcal{A}_i} q$ and $r \sigma \not\rightarrow_{\mathcal{A}_i} q$ detected between $\mathcal{R}$ and $\mathcal{A}_i$, $\mathcal{A}_{i+1}$ is constructed by adding new transitions to $\mathcal{A}_i$ to recognise $r \sigma$ in $q$, i.e. $r \sigma \rightarrow_{\mathcal{A}_{i+1}} q$. 
However, the transition $rro \rightarrow q$ is not necessarily a normalised transition of the form $f(q_1, \ldots, q_n) \rightarrow q'$ and so has to be normalised first. For example, to normalise a transition of the form $f(g(a), h(q')) \rightarrow q$, we need to find some states $q_1, q_2, q_3$ and replace the previous transition by the following set of normalised transitions: $[a \rightarrow q_1, g(q_1) \rightarrow q_2, h(q') \rightarrow q_3, f(q_2, q_3) \rightarrow q]$. 

Assume that $q_1, q_2, q_3$ are new states, then adding the transition itself or its normalised form does not make any difference. Now, assume that $q_1 = q_2$, the normalised form becomes $[a \rightarrow q_1, g(q_1) \rightarrow q_1, h(q') \rightarrow q_3, f(q_1, q_3) \rightarrow q]$. This set of normalised transitions represents the regular set of non normalised transitions of the form $f(g'(a), h(q')) \rightarrow q$, which contains among many others the transition we initially wanted to add. Hence, this is an over-approximation. We could have made an even more drastic approximation by identifying $q_1, q_2, q_3$ with $q$, for instance.

The above method does not work for all TRSs. For instance, consider a constant $A$ and the tree automaton $\mathcal{A} = (\{q_i, q_j, q_f\}, \{A \rightarrow q_1, A \rightarrow q_2, f(q_1, q_2) \rightarrow q_f\})$ and the TRS $\mathcal{R} = \{f(x, x) \rightarrow g(x)\}$. There is no substitution $\sigma$ such that $lor \rightarrow_{\mathcal{A}} q$, for a $q$ in $\{q_1, q_2, q_f\}$. Thus, following the procedure, there is no transition to add. But $f(A, A) \in L(\mathcal{A})$. Thus $g(A) \in R(L(\mathcal{A}))$. Since $g(A) \notin L(\mathcal{A})$, the fixpoint automaton obtained is not an over-approximation of $R^*(L(\mathcal{A}))$.

This constraint may prevent someone from specifying a system, in particular concerning protocols. Unfortunately, to be sound, the approximation-based analysis described in [Genet and Klay 2000] requires using of left-linear TRSs. Nevertheless, this method can still be applied to some non left-linear TRSs, which satisfy some weaker conditions. In [Feuillade et al. 2003] the authors propose new linearity conditions. However, these new conditions are not well-adapted to be automatically checked in the sense that, they are verified as soon as the computation is over. And if these conditions are not satisfied then the computation must be done again by changing some inputs of the approximation technique.

### 3. Main Results – Sound Completion for any Kind of TRSs

The challenge of this section is to describe an alternative way for the technique [Feuillade et al. 2003] in order to make it sound for any kind of TRSs. We first introduce in Section 3.1 the notion of $(l \rightarrow r)$-substitutions and the normalisation related to it. This kind of substitution allows variables to store different values. Second, we present in Section 3.2 an extension of the completion procedure to any TRS for computing sound over-approximations. This algorithm is then detailed on an example in Section 3.3. Third Section 3.5 discusses theoretical and practical aspects for applying the developed techniques to a large class of applications.
3.1 (l → r)-substitutions, Normalisation

In this technical subsection, we define the notion of a (l → r)-substitution suitable for the present work.

**Definition 1.** Let $R$ be a term rewriting system and $l \rightarrow r \in R$. A (l → r)-substitution is an application from $\text{Pos}_X(l)$ into $Q$.

Let $l \rightarrow r \in R$ and $\sigma$ be a (l → r)-substitution. We denote by $l\sigma$ the term of $T(F, Q)$ defined as follows: $\text{Pos}(l\sigma) = \text{Pos}(l)$, and for each $p \in \text{Pos}(l)$, if $p \in \text{Pos}_X(l)$ then $l\sigma(p) = \sigma(l(p))$, otherwise $l\sigma(p) = l(p)$. Similarly, $r\sigma$ is the term in $T(F, Q)$ defined by: $\text{Pos}(r\sigma) = \text{Pos}(r)$, and for each $p \in \text{Pos}(r)$, if $p \notin \text{Pos}_X(r)$ then $r\sigma(p) = r(p)$ and $r\sigma(p) = \sigma(l(p'))$ otherwise, where $p' = \min(\text{Pos}_{r(p)}(l))$ (positions are lexicographically ordered).

**Example 1.** Let us consider $l = f(g(x), h(x, f(y, y)))$ and $r = f(h(x, y), h(y, x))$ represented by the following trees (elements after the comma are the positions in the term; $l$ is represented on the left and $r$ on the right):

![Tree Diagram](image)

Variable positions of $l$ are 1.1 and 2.1 for $x$, and 2.2.1 and 2.2.2 for $y$. Let $\sigma(1.1) = q_1$, $\sigma(2.1) = q_2$, $\sigma(2.2.1) = q_3$ and $\sigma(2.2.2) = q_4$; $\sigma$ is a (l → r)-substitution and $l\sigma = f(g(q_1), h(q_2, f(q_3, q_4)))$ is the term obtained from $l$ by substituting the variable in position $p$ by $\sigma(p)$. Now we explain how to compute $r\sigma$. The minimal position where $x$ [resp. $y$] occurs in $l$ is 1.1 [resp. 2.2.1]. Thus $r\sigma$ is obtained from $r$ by substituting all $x$’s in $r$ by $\sigma(1.1) = q_1$ and all $y$’s by $\sigma(2.2.1) = q_3$. Thus $r\sigma = f(h(q_1, q_3), h(q_3, q_1))$.

As mentioned before, the completion procedure does not work for all tree automata and TRSs. That is why we introduce a notion of compatibility between finite tree-automata and (l → r)-substitutions. The intuition behind the next definition is that different occurrences of a variable may be substituted by different states if there exists a term recognised by all these states, at least. Notice that the condition required below is weaker than the conditions in [Feuillade et al. 2003]. Moreover, it is more general and can be applied to a larger class of applications.
Definition 2. Let $A$ be a finite tree automaton. We say that a $(l \to r)$-substitution $\sigma$ is $A$-compatible if for each $x \in \text{Var}(l)$,

$$\bigcap_{p \in \text{Pos}_l(l)} L(A, \sigma(p)) \neq \emptyset.$$ 

Example 2. Let $A_{\text{exe}} = (\{q_0, q_f\}, \Delta_{\text{exe}}, \{q_f\})$ with the set of transitions $\Delta_{\text{exe}} = \{A \to q_0, A \to q_f, f(q_f, q_0) \to q_f, h(q_0, q_0) \to q_0\}$. Let $R_{\text{exe}}$ be the TRS such that $R_{\text{exe}} = \{f(x, h(x, y)) \to h(A, x)\}$. The automaton $A_{\text{exe}}$ recognises the set of trees such that every path from the root to a leaf is of the form $f^*h^*A$. Let us consider the substitution $\sigma_{\text{exe}}$ defined by $\sigma_{\text{exe}}(1) = q_f$, $\sigma_{\text{exe}}(2.1) = q_0$ and $\sigma_{\text{exe}}(2.2) = q_0$. The tree $t = A$ can be reduced to $q_f$ and belongs to $L(A, \sigma_{\text{exe}}(1))$. Furthermore $t \to q_0$, so $t \in L(A, \sigma_{\text{exe}}(2.2))$. Therefore $\sigma_{\text{exe}}$ is $A$-compatible.

The notion of normalisation and approximation functions are close to the ones given in [Feuillade et al. 2003][Boichut et al. 2005]. Indeed, the definitions below are simply adapted to our notion of $(l \to r)$-substitutions.

Definition 3. Let $A$ be a finite tree automaton. An approximation function (for $A$) is a function which associates a function from $\text{Pos}(r)$ to $Q$ to each tuple $(l \to r, \sigma, q)$, where $l \to r \in R$, $\sigma$ is an $A$-compatible $(l \to r)$-substitution and $q$ a state of $A$.

Example 3. Consider the automaton $A_{\text{exe}}$, the TRS $R_{\text{exe}}$ and the substitution $\sigma_{\text{exe}}$ defined in Example 2. For $\sigma_{\text{exe}}$, an approximation function $\gamma_{\text{exe}}$ may be defined by

$$\gamma_{\text{exe}}(l \to r, \sigma_{\text{exe}}, q_0) : \{ \varepsilon \mapsto q_1, 1 \mapsto q_2, 2 \mapsto q_f \}$$

To totally define $\gamma_{\text{exe}}$, the others (finitely many) $A_{\text{exe}}$-compatible substitutions should be considered too.

The notion of normalisation below is basic. The only difference comes from our notion of $(l \to r)$-substitutions.

Definition 4. Let $A = (Q_0, \Delta_0, F_0)$ be a finite tree automaton, $\gamma$ an approximation function for $A$, $l \to r \in R$, $\sigma$ an $A$-compatible $(l \to r)$-substitution, and $q$ a state of $A$. We denote by $\text{Norm}_\gamma(l \to r, \sigma, q)$ the following set of transitions, called normalisation of $(l \to r, \sigma, q)$:

$$\{f(q_1, \ldots, q_k) \to q' \mid p \in \text{Pos}_f(r), r(p) = f, q' = q \text{ if } p = \varepsilon \text{ otherwise } q' = \gamma(l \to r, \sigma, q)(p), q_i = \gamma(l \to r, \sigma, q)(p.i) \text{ if } p.i \notin \text{Pos}_X(r), q_i = \sigma(\min\{p' \in \text{Pos}_X(l) \mid l(p') = r(p.i)\}) \text{ otherwise} \}$$

The min is computed for the lexical order.
Notice that the set \( \{ p' \in \mathcal{P} \text{os}_X(l) \mid l(p') = r(p,i) \} \) used in the above definition is not empty as soon as \( \forall \text{Var}(l) \) is not empty. Indeed, in a TRS, variables occurring in its right-hand-sides must, by definition, occur in the left-hand side too.

**Example 4.** Following Example 3, \( \varepsilon \) is the unique functional position of the term \( r = h(A,y) \). We set \( q' \) of the definition to be equal to \( q_f \). Thus \( \text{Norm}_{\gamma_{\text{exe}}}(l \rightarrow r, \sigma_{\text{exe}}, q_f) \) is of the form \( \{ A \rightarrow q', h(q?,q??) \rightarrow q_f \} \). Since for \( r \), the position 1 is a functional position and 2 is in \( \mathcal{P} \text{os}_X(r) \), we use the last line of the definition to compute \( q?? \), and \( q? \) is defined by the approximation function \( \gamma_{\text{exe}} \). Finally, we obtain:

\[
\text{Norm}_{\gamma_{\text{exe}}}(l \rightarrow r, \sigma_{\text{exe}}, q_f) = \{ r(1) \rightarrow \gamma_{\text{exe}}(1), r(\varepsilon)(\gamma_{\text{exe}}(1), \sigma_{\text{exe}}(1)) \rightarrow q_f \}
\]

\[
= \{ A \rightarrow q_0, h(q_0, q_f) \rightarrow q_f \}.
\]

**Lemma 1.** Let \( \mathcal{A} \) be a finite tree automaton, \( \gamma \) an approximation function, \( l \rightarrow r \in \mathcal{R} \), \( \sigma \) an \( \mathcal{A} \)-compatible \((l \rightarrow r)\)-substitution, and \( q \) a state of \( \mathcal{A} \). If \( l \sigma \rightarrow^{*}_{\mathcal{A}} q \) then \( r \sigma \rightarrow^{*}_{\text{Norm}_{\gamma}(l \rightarrow r, \sigma, q)} q \).

The proof is obvious. The transitions in \( \text{Norm}_{\gamma} \) are precisely those added to reduce \( r \sigma \) to \( q \).

### 3.2 Over-Approximations for TRSs without Left-Linearity Constraint

This section is dedicated to the proof of the main result and explains how to build a regular over-approximation of \( \mathcal{R}'(\mathcal{A}) \). The following definition presents the construction of a tree automaton \( \mathcal{C}_\gamma(\mathcal{A}_0) \) from the tree automaton \( \mathcal{A}_0 \), the approximation function \( \gamma \) and the TRS \( \mathcal{R} \). This construction is usually named a completion step. Again, the only considered substitutions are \((l \rightarrow r)\)-substitutions.

**Definition 5.** Let \( \mathcal{R} \) be a TRS. Let \( \mathcal{A}_0 = (Q_0, \Delta_0, F_0) \) be a finite tree automaton and \( \gamma \) an approximation function for \( \mathcal{A}_0 \). The automaton \( \mathcal{C}_\gamma(\mathcal{A}_0) = (Q_1, \Delta_1, F_1) \) is defined by:

\[
\Delta_1 = \Delta_0 \cup \bigcup \text{Norm}_{\gamma}(l \rightarrow r, \sigma, q)
\]

where the union involves all rules \( l \rightarrow r \in \mathcal{R} \), all states \( q \in Q_0 \), all \( \mathcal{A}_0 \)-compatible \((l \rightarrow r)\)-substitutions \( \sigma \) such that \( l \sigma \rightarrow^{*}_{\mathcal{A}_0} q \) and \( r \sigma \nrightarrow^{*}_{\mathcal{A}_0} q \).

\[
F_1 = F_0 \quad \text{and} \quad Q_1 = Q_0 \cup Q_2,
\]

where \( Q_2 \) denotes the set of states occurring in left or right-hand sides of \( \Delta_1 \) transitions.

The above lemma shows that a completion step computes an over-approximation of terms obtained by one rewriting step.

**Lemma 2.** Let \( \mathcal{A}_0 = (Q_0, \Delta_0, F_0) \) be a finite tree automaton and \( \gamma \) be an approximation function for \( \mathcal{A}_0 \). Let \( \mathcal{R} \) be a TRS. One has \( \mathcal{L}(\mathcal{A}_0) \cup \mathcal{R}(\mathcal{L}(\mathcal{A}_0)) \subseteq \mathcal{L}(\mathcal{C}_\gamma(\mathcal{A}_0)) \).
PROOF. Let \( t \in \mathcal{L}(\mathcal{A}_0) \cup \mathcal{R}(\mathcal{L}(\mathcal{A}_0)) \). By definition of \( C_\gamma(\mathcal{A}_0) \) one has \( \mathcal{L}(\mathcal{A}_0) \subseteq \mathcal{L}(C_\gamma(\mathcal{A}_0)) \). Consequently, if \( t \in \mathcal{L}(\mathcal{A}_0) \) then one has \( t \in \mathcal{L}(C_\gamma(\mathcal{A}_0)) \). Thus we now assume that \( t \in \mathcal{R}(\mathcal{L}(\mathcal{A}_0)) \). Thus there exists a rule \( l \rightarrow r \in \mathcal{R} \), a term \( t_0 \) in \( \mathcal{L}(\mathcal{A}_0) \), a position \( p \) of \( t_0 \) and a substitution \( \mu \) in \( \Sigma(\mathcal{X}, \mathcal{T}(\mathcal{F})) \) such that

\[
\begin{align*}
t_{0|p} &= l\mu \quad \text{and} \quad t = t_0[r\mu|p].
\end{align*}
\]

Since \( t_0 \in \mathcal{L}(\mathcal{A}_0) \), there exist a state \( q \in Q_0 \) and a state \( q_f \in F_0 \) such that

\[
l\mu \rightarrow^*_{\mathcal{A}_0} q \quad \text{and} \quad t_0[p|q] \rightarrow^*_{\mathcal{A}_0} q_f.
\]

Since \( l\mu \rightarrow^*_{\mathcal{A}_0} q \) there exists an \((l \rightarrow r)\)-substitution \( \sigma \) such that \( l\mu \rightarrow^*_{\mathcal{A}_0} l\sigma \). Furthermore, for each \( x \in \mathcal{V} \),

\[
\mu(x) \in \bigcap_{p \in \text{Pos}(\mathcal{A})} \mathcal{L}(\mathcal{A}, \sigma(p)),
\]

thus the \((l \rightarrow r)\)-substitution \( \sigma \) is \( \mathcal{A}_0 \) compatible. Therefore, using Lemma 1 (by hypothesis, \( l\sigma \rightarrow^*_{\mathcal{A}_0} q \)), one has

\[
r\sigma \rightarrow^*_{C_\gamma(\mathcal{A}_0)} q.
\]

For each variable \( x \) occurring in \( l \) and all positions \( p \) of \( x \) in \( l \), one has \( \mu(x) \rightarrow^*_{\mathcal{A}_0} \sigma(p) \). In particular, for each variable \( x \) occurring in \( l \), \( \mu(x) \rightarrow^*_{\mathcal{A}_0} \sigma(p') \), where \( p' \) is the minimal position where \( x \) occurs in \( l \). Consequently and by definition of \( r\sigma \), one has

\[
r\mu \rightarrow^*_{\mathcal{A}_0} r\sigma.
\]

We are now able to conclude: using (3.1) one has \( t = t_0[r\mu|p] \). Now, by (3.4) \( t \rightarrow^*_{\mathcal{A}_0} t_0[r\mu|p] \). To finish, using (3.3) and then (3.2) we obtain the following derivation: \( t \rightarrow^*_{C_\gamma(\mathcal{A}_0)} t_0[p|q] \rightarrow^*_{\mathcal{A}_0} q_f \). Thus \( t \in \mathcal{L}(C_\gamma(\mathcal{A}_0)) \), proving the lemma. \( \square \)

Let us remark that using well-chosen approximation functions may iteratively lead to a fixpoint automaton which recognises an over-approximation of \( \mathcal{R}^*(\mathcal{A}_0) \). One can formally express this by the following (soundness) main theorem.

**Theorem 1.** Let \( (\mathcal{A}_n) \) and \( (\gamma_n) \) be respectively a sequence of finite tree automata and a sequence of approximation functions defined by: for each integer \( n \), \( \gamma_n \) is an approximation function for \( \mathcal{A}_n \) and \( \mathcal{A}_{n+1} = C_{\gamma_n}(\mathcal{A}_n) \). If there exists a positive integer \( N \), such that for every \( n \geq N, \mathcal{A}_n = \mathcal{A}_N \), then \( \mathcal{R}^*(\mathcal{L}(\mathcal{A}_0)) \subseteq \mathcal{L}(\mathcal{A}_N) \).

The proof is by induction using Lemma 2.
3.3 Completion Example

In this section we explain how our approach works on an example in touch with the mathematical world.

We consider terms defined over $\mathcal{F}_0 = \{0\}, \mathcal{F}_1 = \{\text{Opp}, s\}, \mathcal{F}_2 = \{+\}$ and $\mathcal{F}_{k\geq 3} = \emptyset$.

Here, the symbol $s$ denotes the successor function. For instance, $s(s(0)))$ is the successor of the successor of the successor of 0 and denotes the integer 3. The operator $\text{Opp}$ denotes the opposite value of an integer. For example, $\text{Opp}(s(0))$ is the opposite value of the successor of 0 and denotes the integer $-1$. We use the following TRS to encode addition and subtraction over $\mathbb{Z}$. To simplify notations, we write $(x + y)$ or $x + y$ for $+(x,y)$.

$$\mathcal{R} = \{\text{Opp}(\text{Opp}(x)) \rightarrow x \text{ } (3.5)\}$$

$$x \rightarrow \text{Opp}(\text{Opp}(x)) \text{ } (3.6)$$

$$x + \text{Opp}(x) \rightarrow 0 \text{ } (3.7)$$

$$x + y \rightarrow y + x \text{ } (3.8)$$

$$x + (y + z) \rightarrow (x + y) + z \text{ } (3.9)$$

$$x + 0 \rightarrow x \text{ } (3.10)$$

$$x + s(0) \rightarrow s(x) \text{ } (3.11)$$

$$\text{Opp}(s(x)) \rightarrow x + s(0) \text{ } (3.12)$$

$$\text{Opp}(s(s(x))) + s(0) \text{ } (3.13)$$

Notice that this TRS is not left-linear (Rule (3.7)). We are interested in the following problem: given three integers $a$, $b$ and $c$, are there integers $\lambda$ and $\mu$ such that $\lambda a + \mu b = c$? A basic number theory result states that the answer to the previous question is yes if and only if $c$ is a multiple of the greatest common divisor of $a$ and $b$.

For instance, it is possible for $a = 7$, $b = 3$ and $c = 15$ (since $\gcd(a,b) = 1$). We may prove it using the above TRS. Indeed, from $s^7(0)$ and $s^3(0)$ one can reach $s^{15}(0)$ using $+$, $\text{Opp}$ and rewriting rules. For example, $s^3(0) \rightarrow_{12}^* s(0) + s(s(0)) + s(0)$. Consequently, $s^3(0) + s^3(0) \rightarrow_{(3.12),(3.9)}^* s^6(0)$. Similarly one has $((s^7(0) + s^7(0)) + s^7(0)) \rightarrow_{(3.12),(3.9)}^* s^{21}(0)$. Moreover, $\text{Opp}(s^3(0) + s^3(0)) \rightarrow_{(3.12),(3.9),(3.8)}^* \text{Opp}(s^{21}(0)) + s^{15}(0)$. Therefore, $((s^7(0) + s^7(0)) + s^7(0)) + \text{Opp}(s^3(0) + s^3(0)) \rightarrow_{(3.8),(3.12),(3.9)}^* (s^{21}(0) + \text{Opp}(s^{21}(0))) + s^{15}(0) \rightarrow_{(3.7),(3.10)}^* s^{15}(0)$.

Now we prove that the problem has no solution for $a = 2$, $b = 4$ and $c = 5$ (this is mathematically trivial, the goal is just to illustrate that it can be automatically proved using our over-approximation approach).

We consider for initial terms the language accepted by the following tree automaton $A$ whose states are $q_0$, $q_1$, $q_2$, $q_3$, $q_4$, $q_5$ and $q_6$, whose final states are $q_2$, $q_6$, $q_4$, and $q_7$, and whose transitions are $0 \rightarrow q_0$, $s(q_0) \rightarrow q_1$, $s(q_1) \rightarrow q_2$, $s(q_2) \rightarrow q_3$, $s(q_3) \rightarrow q_4$ (encodes that $s^2(0)$ and $s^4(0)$ are initially known), $\text{Opp}(q_4) \rightarrow q_4$ (encodes that one can compute the opposite value of 4), $\text{Opp}(q_2) \rightarrow q_2$ (encodes that one can compute the opposite value of 2),
\( q_{f_1} + q_{f_2} \rightarrow q_f \) for all final states \( q_{f_1}, q_{f_2} \), (encodes that one can do the addition of two computed integers terms). We want to prove that \( s^5(0) \notin \mathcal{R}^*(\mathcal{L}(\mathcal{A})) \). Some details on the first completion step are given below.

**Rule (3.5)** This rule provides no new transition. Indeed, there is no state \( q \) in \( \mathcal{A} \) such that \( \text{Opp}(\text{Opp}(q)) \) can be reduced in \( \mathcal{A} \) to a state.

**Rule (3.6)** For each state \( q \) one has to add the normalisation of the transition \( \text{Opp}(\text{Opp}(q)) \rightarrow q \). Assume that

\[
\gamma(\text{Rule}(6), \{\varepsilon \mapsto q_1\}, q_1)(1) = q_3.
\]

Then during the completion step, the normalisation of \( \text{Opp}(\text{Opp}(q_1)) \rightarrow q_1 \) adds the transitions \( \text{Opp}(q_1) \rightarrow q_3 \) and \( \text{Opp}(q_3) \rightarrow q_1 \). With similar assumptions on \( \gamma \), one adds during the first completion step \( \text{Opp}(q_0) \rightarrow q_0, \text{Opp}(q_4) \rightarrow q_4 \) and \( \text{Opp}(q_2) \rightarrow q_2 \).

**Rule (3.7)** Since \( q_4 + \text{Opp}(q_4) \rightarrow^*_{\mathcal{A}} q_f \), one has to add the transition \( 0 \rightarrow q_f \) (we may easily verify this is the only compatible \( l \mapsto r \)-substitution).

**Rule (3.8-3.11)** These rules don’t provide new transitions.

**Rule (3.12)** Since \( s(q_0) \rightarrow^*_{\mathcal{A}} q_1 \) and \( q_0 + s(0) \not\rightarrow^*_{\mathcal{A}} q_1 \), one has to add the following transitions (with correct assumptions on \( \gamma \)) \( 0 \rightarrow q_0, s(q_0) \rightarrow q_1 \) (these two transitions are already in \( \mathcal{A} \)) and \( q_0 + q_1 \rightarrow q_1 \). Similarly, one has to add transitions \( q_0 + q_2 \rightarrow q_2, q_0 + q_3 \rightarrow q_3, q_0 + q_4 \rightarrow q_4 \).

**Rule (3.13)** Since \( \text{Opp}(s(q_1)) \rightarrow^*_{\mathcal{A}} q_2 \) and \( \text{Opp}(s(s(q_1))) + s(0)) \not\rightarrow^*_{\mathcal{A}} q_2 \), one has to add the transitions (with correct assumption on \( \gamma \)), \( s(0) \rightarrow q_1, s(q_1) \rightarrow q_2, s(q_2) \rightarrow q_3, \text{Opp}(q_3) \rightarrow q_1, q_1 + q_1 \rightarrow q_2 \) and \( \text{Opp}(q_2) \rightarrow q_2 \).

Similar completion steps lead to the following tree automaton \( \mathcal{B} \):

- States of \( \mathcal{B} \) are \( q_{-4}, q_{-2}, q_1, q_2, q_3, q_4 \) and \( q_f \). Final states are \( q_2, q_4, q_{-2}, q_{-4} \) and \( q_f \), transitions on constants are \( 0 \rightarrow q_0 \) and \( 0 \rightarrow q_f \).
- Transitions with symbol \( s \) are given by the following table:

<table>
<thead>
<tr>
<th>( s )</th>
<th>( q_0 )</th>
<th>( q_1 )</th>
<th>( q_2 )</th>
<th>( q_3 )</th>
<th>( q_4 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( q_0 )</td>
<td>( q_1 )</td>
<td>( q_2 )</td>
<td>( q_3 )</td>
<td>( q_4 )</td>
<td>( q_f )</td>
</tr>
</tbody>
</table>

For instance, \( s(q_2) \rightarrow q_3 \) is a transition.

- Transitions with symbols \( \text{Opp} \) and \( + \) are given by the following tables:

<table>
<thead>
<tr>
<th>Opp</th>
<th>( q_{-4} )</th>
<th>( q_{-2} )</th>
<th>( q_0 )</th>
<th>( q_1 )</th>
<th>( q_2 )</th>
<th>( q_3 )</th>
<th>( q_4 )</th>
<th>( q_f )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( q_4 )</td>
<td>( q_{-2} )</td>
<td>( q_0 )</td>
<td>( q_1 )</td>
<td>( q_2 )</td>
<td>( q_3 )</td>
<td>( q_4 )</td>
<td>( q_f )</td>
<td></td>
</tr>
</tbody>
</table>
The automaton $\mathcal{B}$ is stable by the $C_\gamma$ completion. Consequently, it accepts an over-approximation of reachable terms of $\mathcal{A}$ by $\mathcal{R}$. Since $s^5(0) \notin \mathcal{L}(\mathcal{B})$, we may not have $\lambda.2 + \mu.4 = 5$ with $\lambda, \mu \in \mathbb{Z}$.

3.4 Under-Approximations for TRSs without Left-Linearity Constraint

The main idea (and problem) behind the under-approximations is that one wants the languages of computed tree automata to be in the set of terms reachable by rewriting. Having some conditions on the TRS allows us to prove that a term is actually reachable.

In order to obtain under-approximations, we do not want the completion procedure to introduce unreachable terms. Classically, we then work with injective approximation functions. We define here $\gamma$ to be an injective approximation function from $\mathcal{R} \times (\mathbb{N}^* \mapsto \mathcal{Q}) \times \mathbb{N}^* \times \mathcal{Q}$ into $\mathcal{Q}$. Theorem 2 shows that with such an approximation function, an under-approximation of the set of reachable terms is possible. Before, Lemma 3 presents an intermediary result useful for proving Theorem 2: this result reveals some features of terms recognised by $C_\gamma(\mathcal{A})$ for which there exists a rewriting predecessor recognised by $\mathcal{A}$. In the following, we introduce the notation $NLV(t)$ which for a term $t$ of $\mathcal{T}(\mathcal{F},X)$, denotes the set of non-linear variables of $t$, i.e., the set of variables occurring at least twice within $t$.

**Lemma 3.** Let $\mathcal{R}$ be a right-linear TRS for which $NLV(l) \cap \text{Var}(r) = \emptyset$ for all $l \rightarrow r \in \mathcal{R}$. Let $\mathcal{A}$ be a tree automaton. There exists $t_0 \in \mathcal{T}(\mathcal{F})$ such that $t_0 \in \mathcal{L}(\mathcal{A},q)$ and $t_0 \rightarrow_\mathcal{R} t$, if there exist a ground term $t$ over $\mathcal{F}$, a state $q$ of $\mathcal{A}$ and a function $\tau$ from $\mathcal{P}os(t)$ to $\mathcal{Q}$ such that $t \in \mathcal{L}(C_\gamma(\mathcal{A}),q)$, $t \notin \mathcal{L}(\mathcal{A},q)$ and $\tau$ satisfies the following conditions: (i) $\tau(\epsilon) = q$; (ii) for all $p \in \mathcal{P}os(t)$, $t\|_p \in \mathcal{L}(C_\gamma(\mathcal{A}),\tau(p))$ and, (iii) for all $p \in \mathcal{P}os(t) \setminus \{\epsilon\}$, if $\tau(p)$ is a state of $\mathcal{A}$, then $t\|_p \in \mathcal{L}(\mathcal{A},\tau(p))$.

**Proof.** To simplify the notations we denote by $\Delta_1$ the set of transitions of the automaton $C_\gamma(\mathcal{A})$, $\Delta_0$ the set of transitions of $\mathcal{A}$, and $Q_0$ the set of states of $\mathcal{A}$.

The proof consists of 1) the construction of a term $s_1 \in \mathcal{T}(\mathcal{F},\mathcal{Q})$ such that
that at least. Consequently, there exists $q$ and for each position $t \in \mathcal{T(F,Q)}$ such that

$$t \rightarrow^*_{\Delta_1} s \rightarrow_{\text{Norm}_y(l \rightarrow r,\sigma,q)} q,$$  \hfill (3.14)

2) the construction, by iterating a backward process, of a term $s \in \mathcal{T(F,Q)}$ such that

$$t \rightarrow^*_{\Delta_1} s \rightarrow^*_{\text{Norm}_y(l \rightarrow r,\sigma,q)} q,$$  \hfill (3.15)

3) the proof that

$$t \rightarrow^*_{\Delta_0} r \sigma \rightarrow^*_{\text{Norm}_y(l \rightarrow r,\sigma,q)} q.$$  \hfill (3.16)

First, using (ii) at the position $e$ gives $t_{| e} \rightarrow^*_{\Delta_1} \tau(e)$. Since $t = t_{| e}$ and since $\tau(e) = q$ (by (i)), one has $t \rightarrow^*_{\Delta_1} q$.

Since $t \in \mathcal{T(F)}$ one has $t \neq q$, and every derivation $t \rightarrow^*_{\Delta_1} q$ has the length one, at least. Consequently, there exists $s_1 \in \mathcal{T(F,Q)}$ such that $t \rightarrow^*_{\Delta_1} s_1 \rightarrow_{\Delta_1} q$.

We now show by contradiction that the transition $s_1 \rightarrow q \notin \Delta_0$. Suppose that $s_1 \rightarrow q$ is a transition of $\Delta_0$. Then $s_1 \in \mathcal{T(F,Q_0)}$. Thus, using (iii), $t \rightarrow^*_{\Delta_0} s_1 \rightarrow_{\Delta_0} q$, a contradiction ($t \notin \Delta_0$).

Therefore, the transition $s_1 \rightarrow q$ is in $\Delta_1 \setminus \Delta_0$. By definition of $\Delta_1$ (see Definition 5), there exist $q', \sigma : \mathcal{Pos}_y(l)^* \rightarrow Q$ and $l \rightarrow r \in R$ such that $s_1 \rightarrow_{\mathcal{C}_y(C_0)} q \in \text{Norm}_y(l \rightarrow r,\sigma,q')$ and

$$l \sigma \rightarrow^*_{\Delta_0} q'.$$  \hfill (3.17)

Now by definitions of $\text{Norm}_y(l \rightarrow r,\sigma,q')$ and $\gamma$, each target state of a transition in $\text{Norm}_y(l \rightarrow r,\sigma,q')$ is either $Q \setminus Q_0$, or is equal to $q'$. Since $s_1 \rightarrow_{\mathcal{C}_y(C_0)} q \in \text{Norm}_y(l \rightarrow r,\sigma,q')$, either $q \in Q \setminus Q_0$, or $q = q'$. Because $q \in Q_0$, one has $q = q'$ and $t \rightarrow^*_{\Delta_1} s_1 \rightarrow_{\text{Norm}_y(l \rightarrow r,\sigma,q)} q$.

We are done for (3.14). We now perform an iterative construction. If $s_1 \notin \mathcal{T(F,Q_0)}$, then there exists a position $p$ of $s_1$ such that $s_1(p) \in Q \setminus Q_0$. Thus $s_1(p)$ is of the form $s_1(p) = \gamma(l \rightarrow r,\sigma,q)(p)$. Since $\gamma$ is injective, the only transition of $\Delta_1$ leading to $s_1(p)$ is

$$r(p)(\gamma(l \rightarrow r,\sigma,q)(p.1),\ldots,\gamma(l \rightarrow r,\sigma,q)(p.\ell)) \rightarrow s_1(p).$$

Consequently, the derivation $t \rightarrow^*_{\Delta_1} s_1$ has to conclude by $t \rightarrow^*_{\Delta_1} s_2 \rightarrow s_1$ where

$$s_2 = s_1[r(p)(\gamma(l \rightarrow r,\sigma,q)(p.1),\ldots,\gamma(l \rightarrow r,\sigma,q)(p.\ell))]_p.$$  

So, one has $t \rightarrow^*_{\Delta_1} s_2 \rightarrow_{\text{Norm}_y(l \rightarrow r,\sigma,q)} s_1 \rightarrow_{\text{Norm}_y(l \rightarrow r,\sigma,q)} q$. Now, if $s_2 \notin \mathcal{T(F,Q_0)}$, the same construction can be iteratively applied to $s_2$, and so on. Consequently, one can build a term $s \in \mathcal{T(F,Q_0)}$ such that $\mathcal{Pos}(s) = \mathcal{Pos}(r)$ and

$$t \rightarrow^*_{\Delta_1} s \rightarrow^*_{\text{Norm}_y(l \rightarrow r,\sigma,q)} q,$$  \hfill (3.18)

and for each position $p$ of $s$ such that $s(p) \notin Q$,

$$s(p) = r(p).$$  \hfill (3.19)
We are done for (3.15).

We can begin the last part of the proof. Let $q_1, \ldots, q_n$ be the states occurring in $s$ while reading $s$ from the left to the right. Let $p_1, \ldots, p_n$ be respectively the positions in $s$ of states $q_1, \ldots, q_n$. Notice that the backward construction of $s$ is deterministic. Indeed every derivation from $t$ to $q$ can be split up to

$$t \rightarrow \Delta_t \; s \rightarrow^*_{\text{Norm}_t(l \rightarrow r, \sigma, q)} q.$$ 

It implies that for each $q_i$, with $i = 1, \ldots, n$, one has

$$q_i = \tau(p_i). \quad (3.20)$$

At this stage, $s$ is of the form $r\sigma$ since $\gamma$ is defined for every position of $r$. Now using (3.20) and the hypothesis iii), one has

$$t \rightarrow \Delta_t \; r\sigma \rightarrow^*_{\text{Norm}_t(l \rightarrow r, \sigma, q)} q.$$

The TRS $R$ being right-linear with $\text{NLV}(l) \cap \text{Var}(r) = \emptyset$ for each rule $l \rightarrow r$ of $R$, one can build a substitution $\mu : \text{Pos}(l) \rightarrow \mathcal{T}(\mathcal{F})$ such that:

- For $p \in \text{Pos}(\text{Var}(r))(l)$, one can set $\mu(p) = t'$ and $t' = t|_p'$ with $p' \in \text{Pos}(l|_p)(r)$.

Moreover, since $l|_p \not\in \text{NLV}(l)$, one obtains $\mu(p) = t' \rightarrow_\lambda^{l_0} \sigma(p)$.

- For $p \in \text{Pos}(\text{Var}(l) \setminus \text{Var}(r))(l)$, one can proceed in the following way:

  - if $l(p) \in \text{NLV}(l)$ then one can set $\mu(p_1', \ldots, p_n')$ to $t'$ where $t' \in \mathcal{L}(A, \sigma(p_1')) \cap \ldots \cap \mathcal{L}(A, \sigma(p_n'))$ with $\{p_1', \ldots, p_n'\} = \text{Pos}(l|_{p})(l)$.

- Otherwise, one can set $\mu(p)$ to a term $t' \in \mathcal{L}(A, \sigma(p))$.

By this way, there exists $t_0 = l|_{\mu} \in \mathcal{T}(\mathcal{F})$ such that $t_0 \rightarrow^{*}_{\mathcal{A}_0} q$ and $t_0 \rightarrow R t$, proving the lemma. \qed

The following result shows that each term of the language $C_\gamma(A_0)$ is reachable by rewriting from $A_0$ using $R$.

\textbf{Theorem 2.} Let $A_0 = (Q_0, \Delta_0, F_0)$ be a finite tree automaton. Let $R$ be a right-linear TRS. Given the approximation function $\gamma$ defined at the beginning of Section 3.4, if for all $l \rightarrow r \in R$, $\text{Var}(r) \cap \text{NLV}(l) = \emptyset$ then $\mathcal{L}(C_\gamma(A_0)) \subseteq R^{*}(\mathcal{L}(A_0))$.

\textbf{Proof.} Let $P_n$ be the following proposition:

For all $t \in \mathcal{L}(C_\gamma(A_0))$, if there exists a function $\tau$ from $\text{Pos}(t)$ to $Q$ such that $\tau(\varepsilon) = q_f$ and for all $p \in \text{Pos}(t)$,

$$t|_p \rightarrow^{*}_{C_\gamma(A_0)} \tau(p) \quad \text{and} \quad t[\tau(p)]|_p \rightarrow^{*}_{C_\gamma(A_0)} q_f,$$

and such that $||\{p \in \text{Pos}(t) \mid \tau(p) \in Q_0 \wedge t|_p \not\rightarrow^{*}_{A_0} \tau(p)\}|| = n$,

then $t \in R^{*}(\mathcal{L}(A_0))$.

We prove that $P_n$ is true for all $n \geq 0$ by induction on $n$. To simplify notations, let

$$NR(t, \tau) = \{p \in \text{Pos}(t) \mid \tau(p) \in Q_0 \text{ and } t|_p \not\rightarrow^{*}_{A_0} \tau(p)\}.$$
\( \mathcal{P}_0: \) Assume that \( t \) and \( \tau \) satisfy the hypothesis on \( \mathcal{P}_0 \). We have \( |NR(t, \tau)| = 0 \). In particular, \( \varepsilon \notin NR(t, \tau) \). So, \( t = t_{1e} \rightarrow_{\mathcal{A}_0} \tau(\varepsilon) = q_f \). Since \( \mathcal{A}_0 \) and \( C_{\gamma}(\mathcal{A}_0) \) have the same set of final states, \( t \in \mathcal{L}(\mathcal{A}_0) \).

\( \mathcal{P}_n \implies \mathcal{P}_{n+1}: \) Assume that \( \mathcal{P}_n \) is true for \( n \geq 0 \) and that \( t \) and \( \tau \) satisfy the hypothesis on \( \mathcal{P}_{n+1} \). Since \( NR(t, \tau) \) is non-empty, let \( p \) be a maximal element of \( NR(t, \tau) \) (for the lexicographical order). Then, by maximality of \( p \), one can apply Lemma 3 to \( t_p \). Thus, there exists \( t_0 \in T(\mathcal{F}) \) such that \( t_0 \rightarrow_{\mathcal{A}_0} \tau(p) \) and \( t_0 \rightarrow \tau t_p \). Therefore, there exists a function \( \tau_1 \) from \( Pos(t_0) \) into \( \mathcal{Q}_0 \) such that for all \( p' \), \( t_0 \rightarrow_{\mathcal{A}_0} \tau_1(p'), t[\tau_1(p')]p' \rightarrow_{C_{\gamma}(\mathcal{A}_0)} \tau(p) \). We define the function \( \tau_2 \) from \( Pos(t[t_0]_p) \) to \( \mathcal{Q} \) as follows.

- If \( p \) is not a prefix of \( p' \), then \( \tau_2(p') = \tau(p') \).
- Otherwise, if \( p' \) is of the form \( p'u \), then \( \tau_2(p') = \tau_1(u) \).

By construction, \( t[t_0]_p \rightarrow_{\mathcal{R}} t \) and \( |NR(t[t_0]_p, \tau_2)| = n - 1 \). Thus, by induction, \( t \in \mathcal{R}^*(\mathcal{L}(\mathcal{A}_0)) \).

It follows that \( \mathcal{P}_n \) is true for all \( n \geq 0 \), proving the theorem. \( \square \)

Let \( C_{\gamma}^{(n)}(\mathcal{A}_0) \) be the tree automaton obtained after \( n \) completion steps performed from \( \mathcal{A}_0 \) by using the TRS \( \mathcal{R} \) and the approximation function \( \gamma \). Finally, Proposition 1 shows that the approximation function \( \gamma \) provides a sound under-approximation of reachable terms.

**Proposition 1.** If \( \mathcal{R} \) is right-linear and for all \( l \rightarrow r \in \mathcal{R}, NLV(l) \cap \text{Var}(r) = \emptyset \) then for all \( n \leq 0, \mathcal{L}(\mathcal{C}_{\gamma}^{(n)}(\mathcal{A}_0)) \subseteq \mathcal{R}^*(\mathcal{L}(\mathcal{A}_0)) \), \( \mathcal{L}(\mathcal{C}_{\gamma}^{(n)}(\mathcal{A}_0)) \subseteq \mathcal{L}(\mathcal{C}_{\gamma}^{(n+1)}(\mathcal{A}_0)) \) and \( \bigcup_{n \geq 0} \mathcal{L}(\mathcal{C}_{\gamma}^{(n)}(\mathcal{A}_0)) = \mathcal{R}^*(\mathcal{L}(\mathcal{A}_0)) \).

**Proof.** By definition \( C_{\gamma}^{(n+1)}(\mathcal{A}_0) = g(\mathcal{C}_{\gamma}^{(n)}(\mathcal{A}_0)) \). Consequently, the set of transitions of \( C_{\gamma}^{(n)}(\mathcal{A}_0) \) is included in the transition set of \( C_{\gamma}^{(n+1)}(\mathcal{A}_0) \). Thus \( \mathcal{L}(\mathcal{C}_{\gamma}^{(n)}(\mathcal{A}_0)) \subseteq \mathcal{L}(\mathcal{C}_{\gamma}^{(n+1)}(\mathcal{A}_0)) \).

Now, using Lemma 2, one has for all \( n \geq 1 \):

\( \mathcal{R}(\mathcal{L}(\mathcal{C}_{\gamma}^{(n)}(\mathcal{A}_0))) \subseteq \mathcal{L}(\mathcal{C}_{\gamma}^{(n+1)}(\mathcal{A}_0)) \).

Consequently, by a direct induction, \( \mathcal{R}^*(\mathcal{L}(\mathcal{A}_0)) \subseteq \mathcal{L}(\mathcal{C}_{\gamma}^{(n+1)}(\mathcal{A}_0)) \). It implies that \( \mathcal{R}^*(\mathcal{L}(\mathcal{A}_0)) \subseteq \bigcup_{n \geq 0} \mathcal{L}(\mathcal{C}_{\gamma}^{(n)}(\mathcal{A}_0)) \).

One can prove that for all \( n \in \mathbb{N}, \mathcal{L}(\mathcal{C}_{\gamma}^{(n)}(\mathcal{A}_0)) \subseteq \mathcal{R}^*(\mathcal{L}(\mathcal{A}_0)) \) by direct induction on \( n \) using Theorem 2, and we are done. \( \square \)
3.5 Practical Issues

3.5.1 Approximations for Ensuring Safety

Thanks to the above theoretical contributions, at this point, we have means to compute over-approximations and under-approximations of reachable terms. From a system verification point of view, by representing the set of initial configurations of a given system by a tree automaton $\mathcal{A}_0$, and by encoding its evolution by a TRS $\mathcal{R}$, $\mathcal{R}'(\mathcal{L}(\mathcal{A}_0))$ stands for the set of actually reachable configurations. Given a set of bad configurations encoded by a tree automaton $\mathcal{A}_{Bad}$, in order to verify a safety property, it is enough to decide whether the intersection between $\mathcal{R}'(\mathcal{L}(\mathcal{A}_0))$ and $\mathcal{L}(\mathcal{A}_{bad})$ is empty. So, as shown in Fig. 3.1, under-approximations are useful to show that there is one bad configuration reachable, at least. And computing over-approximations is useful to show that no bad configuration is reachable.

![Figure 3.1: System verification using approximations.](image)

3.5.2 Application to Protocols with Algebraic Properties

The completion procedure in Sect. 3.2 fits with all non left-linear TRSs. However, the user may be interested in developing algorithms to efficiently handle the completion for a particular class of non-linear rewrite rules. In the security protocol analysis framework, the problematic non left-linear rules usually concern the decoding abilities of an intruder and the algebraic properties of some cryptographic primitives. A particularity of such rules is that they are quadratic, i.e., rules where a variable can occur at most twice within the left-hand side of the rule; let mention $x \odot x \rightarrow 0$ for example. For this application field, this section gives an algorithm to efficiently handle the completion on TRSs with quadratic rules, called quadratic completion. This algorithm is then used for the experiments described in Section 4.1.

Recall that each completion step requires the computation of $(l \rightarrow r)$-substitutions compatible with the current tree automaton. In Example 2, the rule in $\mathcal{R}_{exe}$ is quadratic, and the substitution $\sigma_{exe}$ is $\mathcal{A}_{exe}$-compatible because $\mathcal{L}(\mathcal{A}_{exe}, \sigma_{exe}(1)) \cap \mathcal{L}(\mathcal{A}, \sigma_{exe}(2.2)) \neq \emptyset$. This last computation can be done thanks to the square of $\mathcal{A}_{exe}$ by establishing the non emptiness of $\mathcal{L}(\mathcal{A}_{exe} \times \mathcal{A}_{exe}, (\sigma_{exe}(1), \sigma_{exe}(2.2)))$. 

Definition 6. Let $\mathcal{A} = (Q, \Delta, F)$ be a tree automaton. The square of $\mathcal{A}$, denoted $\mathcal{A}^2$, is the automaton $= (Q \times Q, \Delta', F \times F)$ where:

$$\Delta' = \{ f((q_1, q_1'), \ldots, (q_n, q_n')) \to (q, q') \mid f(q_1, \ldots, q_n) \to q \in \Delta \land f(q_1, \ldots, q_n) \to q' \in \Delta \}. $$

Roughly speaking, for TRSs specifying protocols with quadratic rules, the square of a tree automaton – the product of a tree automaton with itself – can be computed by using the square of its predecessor. Computing the square of an automaton allows us to know whether there is a common datum between two states $q$ and $q'$ of the built automaton. The quadratic rules are then linearised, and the values taken by the linearised variables are checked on-the-fly. For example, if variable $x$ occurs twice in a rule, one of occurrences is replaced by a fresh variable $y$ in this rule the left-hand side. Then, this rule can be fired if the states $q$ and $q'$ – taken as values by resp. $x$ and $y$ – share at least a term.

More formally, let $\mathcal{A} = (Q, \Delta, F)$ be a tree automaton. Let $\mathcal{A}^2 = (Q_{\mathcal{A}^2}, \Delta_{\mathcal{A}^2}, F_{\mathcal{A}^2})$ be the square of the current tree automaton $\mathcal{A}$ according to Def. 6. The square of the tree automaton $C_y(\mathcal{A})$ can be computed in the following way: $C_y(\mathcal{A})^2 = (Q_{\mathcal{A}^2} \cup (Q \times (Q' \setminus Q)) \cup ((Q' \setminus Q) \times Q) \cup ((Q' \setminus Q) \times (Q' \setminus Q)), \Delta_{\mathcal{A}^2} \cup (\Delta \times (\Delta' \setminus \Delta)) \cup ((\Delta' \setminus \Delta) \times \Delta) \cup ((\Delta \setminus \Delta) \times (\Delta' \setminus \Delta)), F_{\mathcal{A}^2})$. Note that the square of $C_y(\mathcal{A})$ is based on the square of $\mathcal{A}$.

To decide the firing of a rule, an efficient state-of-the-art algorithm for the emptiness decision (see [Comon et al. 2002] for example) and an adapted data structure updated on-the-fly are used. Doing so, one can decide in a very efficient way whether the language of the squared automaton recognised by $\{(q, q')\}$ is not empty. In that case, the rule is fired with the computed substitution.

Thanks to these new features, a large number of protocols has been successfully validated: NSPK-xor, View-only, and also the Encrypted Key Exchange protocol.
(EKE2) using the exponential operator. All of these improvements are carried out in the next section.

4. Automatic Approximations and Applications for Verifying Cryptographic Protocols

Modelling security protocols by tree automata and term rewriting systems is basic, see[Genet and Klay 2000] for instance. On the one hand, the initial knowledge and synthesis abilities of the intruder are encoded by a tree automaton $A_0$. On the other hand, a term rewriting system $R$ encodes protocol steps and intruder’s analysis abilities. Our main purpose being to automate the protocol analysis in so far as possible, approximations should be generated automatically. The main ideas behind such a fully automatic generation are given in Section 4.1. We then give in Section 4.2 new experimental results obtained with the new version of the TA4SP tool.

4.1 Automatic Generation of Approximations

Notice that a safe and sound abstraction with only two agents [Comon-Lundh and Cortier 2003] is considered.

For each rule $l \rightarrow r$, each $(l \rightarrow r)$-substitution $\sigma$, each state $q$ and each position $p$ one has to define $\gamma(l \rightarrow r, \sigma, q)(p)$. Note that the approximation function is build in order to use finitely many nonces (number used once).

Next $R$ is divided into two parts: $R_1$ that encodes protocol steps and $R_2$ that encodes intruder’s abilities. For rules in $R_2$, $\gamma(l \rightarrow r, \sigma, q)(p)$ is independent of both $\sigma$ and $q$. Moreover, for every pair of rules $l_1 \rightarrow r_1$ and $l_2 \rightarrow r_2$ and positions of $p_1$ of $r_1$ and $p_2$ of $r_2$, one has $\gamma(l_1 \rightarrow r_1)(p_1) \neq \gamma(l_2 \rightarrow r_2)(p_2)$.

For rules in $R_1$, $\gamma(l \rightarrow r, \sigma, q)(p)$ does not depend on $q$ but only on $l \rightarrow r$, $p$ and the value of $\sigma$ on a finite set of variables $\{x_1, \ldots, x_n\}$, representing agents names. The intuition is that one can ensure (by automaton properties) that if $l\sigma \rightarrow^* A_0 q$ then $\sigma(x_i)$ may have a bounded number of values. Furthermore, the injectiveness like for $R_2$ rules is required.

Since there are finitely many rules with finitely many positions, the number of states introduced during completion steps is bounded. Consequently, the completion procedure always stops with that approximation function and then computes an over-approximation. Concerning the under-approximations, roughly speaking new states are introduced each time it is necessary. We refer the interested reader to [Boichut et al. 2005] for more details.

4.2 Experimental Results

This section reports on new experimental results obtained when using the new version of the TA4SP tool.

1 http://www.loria.fr/~boichut/ta4sp.html.
The fully automatic TA4SP [Boichut et al. 2005] tool has been plugged into the high level protocol specification language HLPSL. We have thoroughly assessed the TA4SP tool by running it against some IETF\(^2\) protocols of the AVISPA Library\(^3\) and others from the Clark and Jacob library [Clark and Jacob ?]. The experimental results are reported in Fig. 4.2, below. The diagnostic **SAFE** means that all secrecy properties have been verified for an unbounded number of executions of the initial HLPSL scenario. A contrario, the diagnostic **RMU – Rewriting Model is Unsafe** – relates that there exists an attack against one of the secrecy properties in our unbounded rewriting model. The diagnostic ?? means that no conclusion can be drawn.

Using implemented under-approximations presented in Sect. 3.4, four protocols (NSPK, NSPK-XOR, TMN and LPD-MSR) given in Fig. 4.2 have been diagnosed as flawed and the attack traces have, indeed, been built with other tools of the AVISPA platform. Nineteen protocols, specified in HLPSL, have been shown secure using over-approximations as in Sect. 4.1. Notice that we have successfully applied TA4SP not only to well-known protocols like NSPKL, SHARE, LPD-IMSR, from the Clark and Jacob library, but also to large-scale IETF protocols as DHCP-Delayed-Auth, CRAM-MD5, CHAPv2, TSIG, AAA Mobile IP, etc.

The protocols EKE2, h.530-fix and View-only-untyped use cryptographic operators with algebraic properties: exp and xor. The protocols View-only-untyped and EKE2 have been successfully analysed despite the computation time for the latter. Not so good computation time is better than an inconclusive result, as for h.530-fix. Note that the on-the-fly computation (OFC) in Sect. 3.5.2 has allowed us to check the protocol View-only-untyped when a naive approach was result-less as shown below.

Before concluding this section, let us focus on the interesting but inconclusive result concerning the protocol h.530-fix. In [Basin and Mödersheim S. and Viganò 2003], the authors have detected an unknown attack against the protocol h.530 using OFMC (On-the-Fly Model-Checker). They have then proposed a new version of this protocol: h.530-fix. OFMC has shown this protocol secure for the given scenario. So it is quite challenging to show that this protocol is indeed secure now for an unbounded number of sessions. We have tried to check the new version but, its analysis leads to an inconclusive result. However, it would be interesting to define finer approximations in order to show the safety of this protocol. We plan also to investigate in this direction – notably using a trace reconstruction technique we have developed in [Boichut and Genet 2006].

Table 4.2: Experiments on some secrecy properties using TA4SP

One last word about the computation times of Fig. 4.2: they are indeed not as good as we wished, but we are developing a promising new engine for the completion which gives impressive results. For example, a computation taking four days long has been reduced to forty-five minutes. This rewrite engine is still in progress, but we hope to integrate the next engine within TA4SP in the coming months.

5. Conclusion

This paper presents an essential improvement of [Feuillade et al. 2004] showing how to extend that work to any kind of TRSs. Moreover, we also explained how to automate this approach in a suitable way. In this context we have provided a new tree regular model-checking technique. We also exposed how to use the technique for analysing security protocols, showing that the approach is not a purely domain-theoretic framework. We want to emphasise the fact that all the algorithms have been implemented, giving rise to the new version of the TA4SP tool.
The construction presented in this paper has several interesting features. The automatic generation of approximation functions for security protocols is quite intuitive. Indeed, it can be summarised to the following intuition: "for such a session, normalise in such a way". But, one can wonder how to generate approximations automatically for more complex objects, as Java programs [Boichut et al. 2007]. It would also be interesting to investigate similar approaches for unranked-tree automata that are useful for XML documents analysis. Moreover, a central question arising out of our work is how to combine the approximation-based techniques with existing tree automata regular techniques approaches, in order to get benefit from both approaches.
